Funny...I'm running the '157 at 26 MHz ! Experiencing a little low
frequency noise...working on lowering that but the chip IS locking
up well at 26 MHz. I was under the impression that these babies were
designed specifically for cordless phone products in the 46 - 49 MHz
range. The N divider accomodates ratios 14 bits in length...even beyond
49 MHz with a reference ratio set for 5 KHz step size. Perhaps the
N divider may crap out somewhere before 49 MHz but it seems to be
handling 26 MHz quite well.

850 degrees F isn't all that hot. We use Weller 800 degree tips in all our irons at work (PCB assembly) and they do fine. On some very delicate items we may use 700 degree, and once in a blue moon, 600, but 98% of the time, 800 does the job.

A common error when learning to solder is using a low temperature iron to "avoid damage". Often that causes MORE damage because of the extra long heating time required. With a hot iron, you get on the joint, melt the solder quickly, and you're off before the component has a chance to get hot. Works like a charm.

Egon-

I can't argue the theoretical differences, or whether the TS-830 has some unusual requirement that isn't met by the older tube types.

Over the years, I've used 6146s in several different rigs, from SSB to NBFM, including a repeater. In my experience, all versions work. An individual tube may be better than another, but it doesn't seem to relate to which variation is involved.

One factor that DOES make a difference, is how the plate cap is attached to the wire coming out of the glass envelope. The best method is welding. The older tubes were soldered. After many hours of use, the tube's heat plus the high peak current, causes solder to crystalize. The result is a loose connection at the plate cap. It is possible to resolder, but it is a loosing battle with ordinary solder. (When it occurs, there may be a visible circle, about 1/16 inch in diameter, in the center of the plate cap.)

If you have tubes with soldered plate caps, go ahead and use them. Just be aware of what might happen after a long period of heavy use.

It is probably a good idea to keep both tubes as closely matched as you can.

I checked with someone else who is more knowledgeable in tubes than I and
he said that this could very well be the case. He also pointed out the
differences on an s-meter between some slightly different power outputs...

I still think if push came to shove, I'd just plug it in and go for it.

4779. IF-amplifier for 71MHz

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-19 00:00:00 UTC
From: mikael.landing@teknikum.uu.se
Message-ID: <46520s$5l6@columba.udac.uu.se>
Source record: 110216

Are building a receiver for 1.8GHz with IF at 71MHz. The linear IF-amp Im using is a micro-devices 2601 with digitally adjustable gain-control.
Problem is that when the gain is set to a low value the noise figure gets real bad (It goes up as much as the gain goes down). When set to maximum gain the noise is ok though. But when the gain is set to a high value the amp. goes easily into saturation (Input 1dB compression gets worse with the same amount that the gain goes up).

Does anyone have some suggestion how to solve the problem or know some other better linear IF-amp with AGC-line?

Thankful for answers!

Micke

Karl,
I believe there is a schematic in the manual for my Yaesu 757. I have
since replaced it with an FT-990, not sure if there is one in that
manual or not. I think there was an article in QST a year or 2 ago
which showed the interfaces for Knwd, Yaesu, and Icom. The Yaesu used
a MAX 232 chip, I think. Maybe this will at least start you in the
right direction!
Good luck es 73,

A simple substitution of a 6146B for a 6146A will not result in any
[substantial] increase in output. It will probably just last a little longer.

But, you can crank up the screen voltage (and even plate voltage) on the 6146B
a little and then then you can [safely] get a little more power compared to
a plain 6146.

6146W is simply a [mechanical] ruggedized version of the plain 6146. Intended
for stuff like mobile operation, etc.

Jim, You could have a shorted turn in the transformer. You can check it by disconnecting the loads from the secondarys and seeing if it runs warm! If it does, or if it draws more than 50 or 100 mA from the power line with no load, you'll soon be in big trouble! I do think they run a bit warm in normal operation, mine always did. 73 Tom

Yes they normaly operate very hot, One problem is the high voltage
is on all the time (even in stand by). Also there are a fair amount
of tubes in a small cabinet. I know all the 6L6 audio amps I have,
run very hot.

I am in the process of making a helically-wound 1/2-wave 40M dipole. The form is a 40-inch piece of 2-inch PVC pipe (scrap). I wound about 135 feet of 18-ga wire (close to 1 wavelenght) and I plan to put BIG capacitive hats the ends. I know these things are notoriously narrowband, so I plan to do a bunch of fiddling with the cap-hats and the feedpoint.

Can anyone suggest a good way to feed this beast? I am planning to inductively couple to the center and play with the number of turns and their spacing and position on the radiator.

Can anyone offer any words of wisdom?

You can make this circuit in side of the RS-232 DB25 pins.
This interface is compatible with the software CAT for the YAESU radios.
This is a tested circuit and works fine on FT-840.
It's possible that the circuit works on different radios.....

Transcription for English by John KB2LJJ
From: KB2LJJ@KB2LJJ.NJ.USA.NA

Isto pode ser feito dentro da propria ficha de 25 pinos.
Esta interface e compativel com o software CAT para os radios Yaesu.
O esquema acima foi exprimentado no FT-840 e trabalhou,o software de
controlo total (ou quase) do radio e'que ainda n^Do fiz,brevemente
logo tentarei fazer.
E bem possivel que esta interface funcione com outros radios da
yaesu com CAT.

>You need no
>ground whatsoever with a halfwave vertical antenna.

Don,

Sorry to say so, bot you are wrong here. it is true, that the radiation
resistance of a halfwave is higher, and hence losses induced by a poor
ground in the vincinity of the antenna (no or little radials)
is less than for a shorter antenna.

But if you look into the problem of the radiation pattern, you will find,
that it is also degraded above poor gound.

Thanks for the suggestion Gary..
This was one of my thoughts ...line TX and RX..
Most of the replies have suggested that I should be safe with a
relatively short run of wire (<= 15 ft) especially going back to the
trunk. Of greater concern perhaps is the RF from the subject TX getting
into the remote lines however shielding should reduce those chances
substantially, not to mention that the antenna sits outside of the
trunk.
I may stick the proto in as-is and see how it goes.
If I experience any problems then I'll look at using drivers and
receivers...probably at 12 volts...maybe the 1488 and 1489.

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first

antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

What country does "kennedy@aol.com" live and how far from what
border? 0.2 MHz between channels does not sound as if both stations
are in the US. I believe that the FCC regs have the frequencies
divided by 0.8 MHz between 88 & 108 MHz.
In any case I would suggest a phased vertical array for best gain and
f/b ratio, but what do I know? I missed the original post...

4809. 40m vertical - How to mak

"mail sometimes bounces here, please resend if needed!"

Tim, I am thinking about building a "stealth" 40m vertical, with some
pieces of 10 foot conduit that I would fold over when not in use, then
go out and elevate it after dark, sonce we are not supposed to have
visible outdoor antennas. Along the back fence seems like a perfect
spot, since I could stow it there when not in use. I am planning to make
it with swivel joints simply made from two nuts and bolts at each
junction. Three pieces will give me almost 30 feet, and then add a
3 foot top section of wire or a telescoping rod to make it about 33 feet
long. The radials will be tricky, since they will have to be temporary
ones. I think they are supposed to be 5% longer than the radiator,
right?

IYWMN>Tell me what you know about 40m verticals, I've been told that ground
IYWMN>radials acutally function better above ground. I want to build the best
IYWMN>40m vertical I can. What do you have to share?

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

From: mfogarty@netcom.com
Message-ID: <mfogartyDGt3n9.FxL@netcom.com>
Source record: 110116
Cross-posted to: rec.radio.amateur.equipment,rec.radio.scanner,rec.radio.amateur.homebrew

Folks,

I'm new on the amateur radio scene and need some advice. I'll be going to Hong Kong soon and am interested in shopping for an HT. What can you advise me about:

* Brand
* available frequencies
* legalities
* costs

Even if you don't know anything about "export only" HT's or Hong Kong, I'd appreciate your responses about Brands and costs. I'm planning to spend about $400-500 in HK on such a unit.

I've got friends who will guide me through the licensing process and hook me up with the local Ham groups (Bay Area). I intend to go legit and certainly wouldn't want to break any laws by importing something with extra frequencies ;-)

Imagine, though, that you could pick up anything available in the $400-500 range. What would you get?

Thanks,

Mike

>to Hong Kong soon and am interested in shopping for an HT. What can
you
>advise me about:

I'd save myselft the trouble and buy from a stateside distributor, I've heard of guys buying overseas HF gear with features or bands not avail. in U.S but I've never heard of any great bargains. What you save by shopping Hong Kong may cost you quickly if you have a problem or need an accessory for the radio.

I have a Kenwood Dual band HT and like it alot.

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so
the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

All computers generate RFI. The elimination of RFI is next to impossible however it can be reduced greatly by shielding the components of the system.
Some computer cables are not shielded as well as they could/should be. Keyboard cables are generally a weak point. RF chokes at both ends of all cables as close to termination as possible will limit these "antennae's" interference.
The case of the computer is very important. Consider it very similar to the case of a transmitter. Plastic or composite cases provide very little RF shielding. An all metal case is best and make certain that the mating surfaces are free of paint and other insulating materials. This includes the power supply cage. Locate the case as far away from your transceiver as possible.
Monitors are also a prime source of RFI. Adequate shielding is generally supplied on the sides but the other four surfaces are lacking. Locate the monitor as far away from your transceiver as possible and preferably on the same horizontal plane.
Hope this helps

Well, the best way to jam a station is with a bazooka. And you will surely be able to put up with the fact that not only the FCC will dislike you.

Otherwise, since the reputation of amateur radio is suffering from lunatics like you, just go away.

> Stan Kwong

Stan:

I assume from your posting your looking to jam a commercial station
since you wanted to "jam" them in order to hear another. I doubt you
have the funds nessesary to actually create a high powered jamming
signal, your only other option would be to destroy the radio stations
transmitter or antenna.

Either solution has the potential to land you in jail.

If your really sincere about trying to receieve another station, but
can't due to interference from another. Then let your posting state
that. Your much more likely to get help in designing a filter or
antenna than advise on criminal activity.

4822. Megaohmmeter Schematic Wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-21 00:00:00 UTC
From: Bill Webster <webstwl@cat.com>
Message-ID: <46bb26$mh6@vixen.cso.uiuc.edu>
Source record: 110122

This request doesn't have anything to do with ham radio but I'll bet there are some people with that interest that can help me. I am looking for a schematic for a megaohmmeter to measure moisture content of wood. The commercially made ones usually measure from .1 or 1 megaohm to 10,000 or 100,000 megaohms. They usually read this entire range of resistance on one logarithmic scale (a meter movement) that is labeled with "percent of moisture content". The more advanced
meters are digital. I saw one schematic in Fine Woodworking magazine that used an op amp but it had 5 linear ranges instead of one logarithmic so it would not be as convenient to use.

Thanks,

Bill Webster

Not a good idea. Besides being something the FCC would put you in jail for, it won't help your plight. Even if you *could* come up with the kind of equipment necessary to jam a commercial broadcast station, your 'jammer' would have to be more powerful that the station itself. Guess what happens next ? your 'jammer' now blocks out the nearby station you want instead of the original station. Its a lose - lose situation. What you *could* do however, is get yourself a more selective receiver (*much* cheaper that legal counsel -especially in sue-me USA)

Source record: 109986

HI there,
I'm back with my 2 meters SSB rig project.

I have a few questions for the worldwide amateur community :-)

1. Does the use of a 41-43 and 10.7 MHz IFs seem a good choice ?
2. Every frequency synthezisis in that rig is locked on a TCXO at 12.8 MHz
therefore : a x8 multiplication should be done with a standard frequency
multiplier or a PLL ?
3. What is the noise floor of a TCXO ? (in dBc)
4. My last IF is 7.5 kHz and is then post-processed by a 56001 DSP.
5. Is it worthy to lock a 10.625 MHz XCO to the TCXO ? to reduce phase noise ?
6. Does anybody know how to digitally demodulate FM ?
7. What is the bandwith of a 3 kHz deviated FM signal ? (12.5 kHz ?)
8. Does anybody know of a high dynamic mixer that would be useful at 140 MHz?
9. What is the IMD of a dual-gate FET used as a mixer ?

Well, I guess that would be all for today :-)

Iwould prefer an answer by email rather than news, since I barely have
the time to read them.
Anyhow, thank you in advance for any clue.

>
> NICHOLAS MESSINA YPSE19A@prodigy.com

The best bet would be to build the antenna that is listed in the manual
that you recieved with your FM 10. Mine shows instrutions to build a
1/4 wave antenna. Also what are you using for a power supply. Range
can be increase slightly by running the unit at 9 to 13 volts on the B+
input. The BA 1404 has a 3 volt regulation that will keep it happy but
you can run them on a 12 volt well regulated supply.

If all this is done you should get more range without adding a amp and
possibly running into problems with the feds.

Also be sure to pick a clean frequency. Not only will you cut down the
range if you dont but you may cause interference to a licensed broadcaster,
a definate no, no.

Well, you can anyhow use a down-mixer instead of a divider. That would
keep you reference at 5 kHz.
If you have problems with side bands, why not use a '159 chip ? It has
an analog detector together with a coarse error signal, that would
surely reduce greatly your sidebands problems.
BTW, this a a data I'm interested in : what is the reference level that
can pass through a sample/hold phase comparator ? Normally, if connected
to a JFET type OP-amp which a near infinite Zin, it should generate none.
Or does it ?

While I don't doubt that you have a single part locking at 26 MHz, the
fact remains that the data sheet states an Fmax for the MC145157 of 20
Mhz. That is likely to be a conservative estimate, given that it is a
production part.
The one that you have may work at room temperature, but what happens
when you build up a couple of dozen of these, and then put them in
cars. Since you're in Canada, I would expect that these will get
pretty cold in the winter, at night. What happens when the circuit
gets to -40C? I would guess that the '157 will lock below 20 MHz, but
it might not work at 26 MHz. Just something to look out for.
You might want to consider some ot the National Semiconductor
PLLatinum series parts. Very low current, and there is a 2 loop part
that runs to 510 MHz on both loops.

If you design to "typical" specs, the Motorola spec sheet suggests
the part will work to something like 26MHz.

However, if you want a design that works reproducibly over a range
of temperature and voltage conditions, you can't design to
typical specs. Even manufacturing variations may make it
that one '157 works at 26MHz and another doesn't. The '157
is not even suggested in the Motorola spec sheet to work at
49MHz; they have other parts for this.

The Motorola specs for the '157-2 (the lastest, greatest) specifies
Fmax as:

Vin = 500mV p-p ac-coupled sine wave, Vcc=5V: 15MHz
Vin = 1V p-p ac-coupled sine wave, Vcc=5V: 20MHz
Vin = Vss to Vdd square wave, Vcc=5V: 22MHz.

For Vcc = 9V, you can get up to 25MHz, but that's it.

The earlier parts, like the one Rick probably used, are specified
much lower.

The above is a very simplistic concept based on the notion that "all computers generate RFI" and all solutions are sheilding based. This is too simplistic to be a truth.

Metal enclosures are good.

Grounding electronics to metal enclosures is not always good as it often couples the noise right into the enclosure and out into the world. Gotta try it both ways to know which works best. Isolating the electronics from the enclosure worked best for our last project that went thru FCC testing.

But no pound of cure works as well as an ounce of prevention. RFI noise comes from circuits. Fast digital signal edges can be nasty noise makers. A solution is to slow these edges, but this is not a solution for your off-the-shelf PCB motherboard.

I was in Hong Kong this summer, staying in the Causeway Bay area. I
was completely surprised by the number of authorized Icom dealers in
the city. It seems like most if not all camera/electronics stores
sell Icom. I saw some Kenwood, Standard, etc.
Prices were never ever posted- there were coded tags on the items, and
the clerk would tell you, or show you a calculator with the amount. In
my experience, prices were similar to here in the US, in most cases
higher in HK. Some observations:
1. They had a lot of older stuff- dusty in fact. 95 percent was at
current "high rent district" list price. One store, Wilson Camera,
8 Great George St, was giving decent prices on older gear that was
getting dusty.
2. Most if not a □□ll of the gear was in the Asian/Japan
models- 440 gear ran on 430, and there is a great tendency for
the extended recieve we see on US 2M gear to be disabled.
3. Prices as I say were about US or more.
4. There will be a real warranty problem, unless you ship
it back to the dealer in HK
5. I believe the hma radio dealers in HK cater to tourists, such
as the Japanese, who have high prices at home, and would
benefit from the lower taxes, etc. in HK.
6. I am not sure what if any ham operating is done in HK- in China,
there may still be restriction on private stations. In HK, I saw
a business (actually a Chinese dining room) running on Yeasu HTs
on 145.00 Mhz.
7. There were some odd and ends of other brands of gear, even at
the airport gift shop- brands I had not heard of.
8.
My big buy in 2 weeks a was an Icom BP24 I found in a pile of
older packs at Wilson. I paid $67US for it, thinking it was
the last one on earth. On the same trip, I bought a copy of CQ
magazine for $11.00 US and found Ross Distributing with the same packs,
price.

Would I go back- yes. Buy some gear- maybe. Fun place- I have never
been in more Ham Radio dealers in my life.

73,
Erik

>are in the US. I believe that the FCC regs have the frequencies
>divided by 0.8 MHz between 88 & 108 MHz.

US channel assignments are 200 kHz apart. But *in the same market*
the FCC assigns stations with first, second, and third channel guard
bands based on certain mileage separation standards. Thus, *in the
same market*, you won't find FM stations on adjacent channels, instead
they'll be 800 kHz apart as you note. But this fellow is trying to
receive a station in a *distant market*. That can be on an adjacent
channel with a station in his local market. The separation rule for
stations on first adjacent channels is 75 miles. Since he says the
station he wants is 100 miles away, that's within the FCC guidelines.

> In any case I would suggest a phased vertical array for best gain and
>f/b ratio, but what do I know? I missed the original post...

Something everyone seems to be missing is that most FM broadcasting is
done with *circular* polarization. Vertical polarization is not used
(except as a component of circular polarization). In the beginning,
only horizontal polarization was allowed for FM (and TV), but the FCC
allowed circular polarization for either a couple of decades ago and most
FM stations switched. A few TV stations switched too, but most of them
are going back to horizontal (including my station, CP presents problems
for TV signals when the receiving antennas aren't CP, ghost city).

Anyway, for FM stations, there is an advantage to using circular
polarization in that they are receivable both on home horizontal
polarized antennas and on auto vertical antennas. So nearly all
FM stations use CP, but this makes a simple pattern nulling antenna
more complex. If you can't arrange a null in both the vertical and
horizontal planes, and phased properly, you won't get more than a
3 db null on the station.

One option is to build a CP antenna cut to the channel of the desired station. If the polarization sense of the two stations is different, you'll get up to a 30 db null on the reverse polarization sense. If they're the same sense, at least you'll get signal cancellation on any reflected signals from the undesired station since reflection reverses the handedness of a CP signal, IE LHCP becomes RHCP after a reflection. That can help a lot when trying to separate signals not on the same line.

>I used see a static eletric discharge on my rf cable connector.
>I would like to talk about and change experiences about storms, lightning and
>vertical antennas. I am very afraid of it.

You're right to be alarmed. Lightning can be a great hazard if station layout isn't done properly to guard against it. But if the proper steps are taken you can even continue to operate during direct strikes. Those steps may be extreme in some cases, but it can be, and is, routinely done in the broadcast field.

I need to know some things to be helpful. The first thing I want to know is what floor of the building houses your station. Considerably different steps have to be taken if you are on a lower floor than if you are on the top floor (top floor is usually easier). I need to know the construction of your building. Is it steel frame with curtain walls, or is it poured monolithic with mesh reinforcement? I assume that it is steel with curtain walls at that height, but I need to know for sure. I also need to know the grounding system of the building, is it driven steel piers with a Ufer foundation, or is it block poured on grade? I'd expect the former. I also need to know about the cable chases used to feed the antenna from your station, and about how power distribution is done in the building.

Well, that's enough for now. With that information in hand, I can start to ask the questions needed to give you lightning protective advice.

>Tell me what you know about 40m verticals, I've been told that ground
>radials acutally function better above ground. I want to build the best
>40m vertical I can. What do you have to share?

This question really belongs over on the antenna group, but I'll quickly say that tests have been done with elevated feedpoints (and elevated radials), and while there is still some controversy, elevated systems appear to be better. The reason they seem to be better is that they get the high base currents up away from lossy Earth. Some tests have shown that as few as 4 elevated radials have as low a loss as 24 in ground radials.

You can't raise the radials without elevating the feedpoint, however. If you don't, results will be bad. Raising the feedpoint for a 40 meter vertical isn't always mechanically simple, and raised radials are unsightly, and can be a hazard to people walking under the antenna. Tradeoffs.

: sell Icom. I saw some Kenwood, Standard, etc.
I've visited Hong Kong several times and purchased a radio or two
on occasion. Let me compare/contrast my experiences.

: Prices were never ever posted- there were coded tags on the items, and
: the clerk would tell you, or show you a calculator with the amount. In
: my experience, prices were similar to here in the US, in most cases
: higher in HK. Some observations:
: 1. They had a lot of older stuff- dusty in fact. 95 percent was at
: current "high rent district" list price. One store, Wilson Camera,
: 8 Great George St, was giving decent prices on older gear that was
: getting dusty.
Yes. Amazing how old some of the stuff was. Actually worked to
my advantage in one case since I wanted a model that was no
longer available in the U.S.

: 2. Most if not a □□ll of the gear was in the Asian/Japan
: models- 440 gear ran on 430, and there is a great tendency for
: the extended recieve we see on US 2M gear to be disabled.
Major problem here. Watch out for versions of equipment that
are setup for non-US markets. Its not always easy to figure
out in advance, either.

: 3. Prices as I say were about US or more.
I'd give them more credit than that...but its not always easy to
tell the rockbottom price with extensive negotiation.

: 4. There will be a real warranty problem, unless you ship
: it back to the dealer in HK
: 5. I believe the hma radio dealers in HK cater to tourists, such
: as the Japanese, who have high prices at home, and would
: benefit from the lower taxes, etc. in HK.
Actually, I am not sure WHO they really cater to. The prices
I've seen in Tokyo are roughly equivalent to Hong Kong.
Exchange rate would influence this, of course.

: Would I go back- yes. Buy some gear- maybe. Fun place- I have never
: been in more Ham Radio dealers in my life.

Check.

With 50V as a supply, you are essentially looking for a current
limiter. The original 240 Ohms was the correct value but it would be
dissipating about 20 mA x 50V = 1,000 mW or 1W. No wonder it burned
out. The current to the LED is not so critical but what you could use
a 220 or 270 Ohm 2W resistor.

>d010421c@dcfreenet.seflin.lib.fl.us

Sorry, I screwed up. I should not answer questions when I am half
asleep. You are looking for a current limiter but 50V/20mA makes about
a 2.5K resistor and the dissipation is about 1W. When the 1/2 W
resistor "smokes" the red turns brown on the color code, so it
probably was not 240 Ohms. Use a 2W 2.2K or 2.7K. My apologies if my
prior posting 5 minutes ago caused any problems.

I would like to add to this thread - I was there not too long ago and I got the feeling many stores were more "communications" stores. They had ham, two way, commercial HF, you name it. Whatever you wanted, whoever you were, they were happy to sell it to you. Perfectly legal, of course, as it would be in the US, as long as you didn't try to use it here, or in HK. I suspect the HK government keeps after toursts trying out their new toys before they leave!

I also found the HK shop keeper's to be the nastiest, most disinterested, discourteous S.O.B.'s I have EVER run into. It was so bad I asked my hotel manager what I was doing wrong. He said "probably nothing", adding "being Caucasian and wanting less than 10 of anything was not a good combination for many sales people; a serious problem in HK". All of this right after visiting Tokyo where the HAM (REAL ham) stores where SO polite and friendly I literally could not believe it.

I agree with Tim. I've been to HK several times on business trips and it is not worth the hassling of dealing with the salesmen over there (prices are not fixed and you have to deal, yes as in bargaining!). Also there is the problem of the warranty. I don't think any of the major brands (K,I,Y) honor warranties of any equipment bought overseas. What I have bought though are accessories. Bring your AES catalog to check the price differences. Some things are cheaper there but others are around the same or even higher depending on the store. Another suggestion is to get away from the Nathan Rd. stores, those are usually overpriced.

Have fun in HK.

>>>You need no
>>>ground whatsoever with a halfwave vertical antenna.

>A halfwave antenna *does not require ground* to function.

Hi Gary,

So you both are not right.

>A halfwave vertical is perfectly content to function properly
>in *free space*.

Any length of antenna radiates and is happy to work in free space. The lack of resonance only meens that you will have to do something to get a real feed point impedance. And the existence of a 5/8 antenna shows that sometimes it is better to have a non-resonant antenna rather than an endfed dipole, which needs a high-ratio transformer, wich in turn is a source of problems.

>That counterpoise *can* be Earth, but it doesn't have to be.

Read a text book, and you find that the 1/4 wave and the 1/2 wave antennas behave similar over lossy ground, only that the losses are less for the latter due to its higher radiation resistance (not to be confused with the feed point resistance). There is no fundamental difference, as you are trying to make out.

Think of a walkie talkie: no half wave, no quarter wave or counterweight, but it works.

The '157 is spec'ed at 15 MHz for sine wave and 22 MHz for 5V P-P
square, running from a 5V supply. Your circuit may not continue
to operate correctly when you install it in the radio and it gets
warmed up, etc. It is does work for you, great.

>Maybe this is pushing it to its limit.

Probably

>> >You might want to brush up on your personability skills...
>> >"...simple minded synthesizer..." and your approach in general ceratinly

As has been already pointed out, the "simple minded" referred to the
synthesizer not to you.

>> >don't contribute positively to the spirit of homebrewing !

My postings are "informational"; I don't claim they are "motiviational".

>What is simple minded about a PLL/Loop Filter/VCO when properly
>designed ? I didn't intend on building up some half-assed "well, it

Well, a single loop, integer divider PLL synthesizer is about the
most simple architecture of its kind. Most people at least use
an offset loop or fractional N. In this case, it is, in the long run,
simpler to use a more complicated architecture that is appropriate for
the application than to attempt to push a simple one to its limits.

>kinda works" board. That was the intent of the original post...tell me
>what I need to know and/or HELP me design a solid performer !
>If you don't want to get involved in a positive way, say nothing !
>Perhaps I'm being a bit anal retentive but the net seems to be full
>of the "I can tell you you're wrong but I can't tell you how to
>do it right" types.

I told you how to do it right: use crystals. If you want to
know how to do it right with a synthesizer, look at the schematics
of commercially available ham equipment.

>I suggest that your delivery is somewhat abrasive...try having some
>compassion for those of us who are attempting to learn. Nothing is more

There is nothing compassionate about letting someone go off and
apply to simple technology to a complicated problem.

>of a turnoff than having someone who comes off like a "know-it-all"
>burst your ballon. Albeit, you may know your stuff *BUT* your delivery
>needs some honing.

4856. Need Postscript to HP-GL Translator .. Suggestions ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-23 00:00:00 UTC
From: daveb@buffnet.net
Message-ID: <46h37b$232@buffnet2.buffnet.net>
Source record: 110017

Greetings,

In need of a translator that will convert poscript files to HP - GL (Laserjet 4L).
I'm hoping that someone knows of a freeware/shareware version that will do
the job.

Thanks

daveb@buffnet.net

4857. Radio Shack Pro-51 Mod needed, Please!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-23 00:00:00 UTC
From: aviator270@aol.com
Message-ID: <46fb35$j3j@newsbf02.news.aol.com>

Does anyone know how to open the freqs on the RS pro-51?
If its not possible please let me know.

Thanks in advance!!

4858. '95 Handbook problem, need email or phone reference

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-23 00:00:00 UTC
From: psoper@encore.com
Message-ID: <DGx6MD.GBC@encore.com>
Source record: 110019

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

4860. Want to filter out stupid radio station

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-23 00:00:00 UTC
From: ez041502@dale.ucdavis.edu
Message-ID: <46gnkq$k6l@mark.ucdavis.edu>
Source record: 110021

I posted before about jamming a radio station. I wasn't that
serious. I just wanted to express my intense dislike of "young"
country. (I won't call it music, that'd be giving it too much credit.)
I have since gotten advice to ask about how to filter out the hated
station or to get a "more selective receiver". Now does anyone have any
more information on these perfectly legal solutions?

4861. Re: Modulation transformer question

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-23 00:00:00 UTC
From: 75364.1053@compuserve.com
Message-ID: <46h229$1vo@dub-news-svc-6.compuserve.com>
Source record: 110022

Joel,

An old trick used occasionally in amateur AM homebrew transmitters of the past was to use an audio output transformer in place of the modulation transformer. The high impedance primary looked at the final amplifier plate(s) and the low impedance secondary was driven from an audio amplifier of sufficient output power to fully plate modulate the transmitter. This was equivalent to connecting two transformer secondaries back-to-back since in those days, most of the audio amps used vacuum tubes and drove the load with an output transformer. You used an old public address amplifier as your plate modulator. It might be easier to find an output transformer than a modulation transformer. Some guys even used power transformers to do this, the gov't surplus 400 cycle transformers from military equipment were also used (and weren't too shabby!).

..those were the good old days!

Looking for the following items to complete a few languishing projects:

1. 2 3/8 - 2 1/2" diameter phenolic coil form at least 2" in
length (if its longer I can always cut it down) OR the real thing, L6
(160 meter L-section output coil) from a Globe King 500.

2. Neutralizing capacitor such as National type NC-800 or NC 150, etc.
or Millen no. 15011 or EF Johnson Type N

3. Amplifier shield/fan assembly from a Globe Champion 300A or 350
(I need the entire assembly)

4. Not a part -- but also looking for a Hammarlund SPC-10

Thanks .. Grant/NQ5T

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.

Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so
the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

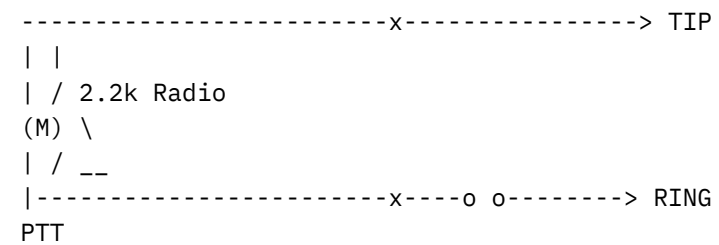
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:



The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

>used a 1/2 watt. According to a an article on LEDs, I was supposed to use
>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be

correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

Gary

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit
current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

The radio remains intact...I just inject the VCO signal further up the
line.
Hmmm... the '157 I have here is running at 26 Mhz !!

>

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it

kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"
burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control
> Symposium paper. I am trying to contribute to homebrewing by saving
> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph
exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off

the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)

or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

: >advise me about:

: I'd save myselft the trouble and buy from a stateside distributor,

Comments from a "Stateside distributor", who has had experience both ways
...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in existance. However, you can find real bargains in Hong Kong on things that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me know if the view is still as grand as it was on Christmas Day of 1972 ... and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the above, I speak for the Amateur Radio community in general, and I think that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and
it is not worth the hassling of dealing with the salesmen over there
(prices are not fixed and you have to deal, yes as in bargaining!).
Also there is the problem of the warranty. I don't think any of the
major brands (K,I,Y) honor warranties of any equipment bought
overseas. What I have bought though are accessories. Bring your AES
catalog to check the price differences. Some things are cheaper there
but others are around the same or even higher depending on the store.
Another suggestion is to get away from the Nathan Rd. stores, those
are usually overpriced.

Have fun in HK.

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.
Ian

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so
the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a

good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

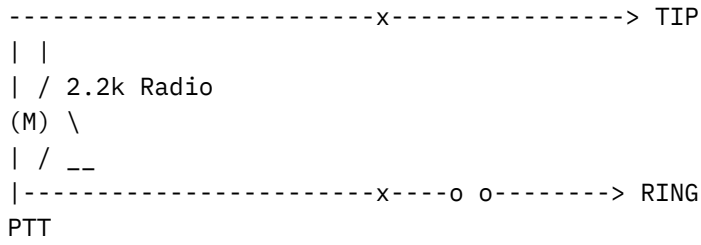
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:



The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

>used a 1/2 watt. According to a an article on LEDs, I was supposed to use
>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

>out. The current to the LED is not so critical but what you could use
>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit
current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

> >Hugh Duff VA3TO Toronto

>
> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"
burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control
> Symposium paper. I am trying to contribute to homebrewing by saving
> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph
exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from

the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

area is going to bouce some of the signal into the first antenna. The more random signals you have bouncing around, the less likely you'll be able to null out the offending station. Good luck.

73's.

Nitpick mode ON:

20 dB is a 100:1 power reduction. 10 dB is 10:1.

>

When I was in college, I had a vacuum tube operated FM clock radio.
I discovered that the LO radiation on it was so bad that it would
wipe out radios in my dorm room or next door if it was tuned 10.7
MHz. lower in frequency. I had lots of fun silencing my roommates'
(and neighbor's) radios when they listened to music I didn't like.
They never figured out what hit them!

4870. Looking to Hear From Builders of Hamcom Interface

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-24 00:00:00 UTC
From: butch@maestro.maestro.com
Message-ID: <DGxIKx.Jp8@maestro.maestro.com>
Source record: 110031

Hello,

I would like to hear from individuals who have built the interface for
the Hamcom interface. I would like to hear your problems as well as parts
and also if you built pc boards?

I would like to add to this thread - I was there not too long ago and I
got the feeling many stores were more "communications" stores. They had ham,
two way, commercial HF, you name it. Whatever you wanted, whoever you were,
they were happy to sell it to you. Perfectly legal, of course, as it would be

in the US, as long as you didn't try to use it here, or in HK. I suspect the HK government keeps after toursts trying out their new toys before they leave!

I also found the HK shop keeper's to be the nastiest, most disinterested, discourteous S.O.B.'s I have EVER run into. It was so bad I asked my hotel manager what I was doing wrong. He said "probably nothing", adding "being Caucasian and wanting less than 10 of anything was not a good combination for many sales people; a serious problem in HK". All of this right after visiting Tokyo where the HAM (REAL ham) stores where SO polite and friendly I literally could not believe it.

From: ab419@freenet.toronto.on.ca (Randie Kochals)
Subject: 4CX1000 Prices?

I am looking around for an Eimac 4CX1000a tube and was wondering
what the going price should be for new and used. If any of you
have seen for sale, or have recently bought one of these, let me
know what I should be prepared to pay.

Thanks

Subject: Need Postscript to HP-GL Translator .. Suggestions ?

Greetings,

In need of a translator that will convert poscript files to HP - GL (Laserjet 4L).
I'm hoping that someone knows of a freeware/shareware version that will do
the job.

Thanks

Date: Mon, 23 Oct 1995 21:06:12 GMT
From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

From: giles@wormwood.demon.co.uk (giles)
Subject: 50MHz transmitter frequencies for UK

I have recently passed my RAE and instead of lashing out on expensive
equipment ,I am going to do some homebrew QRP projects together with
appropriate instrumentation -- see Practical Transmitters for
Novices. What I should like to know:

1) What are best channel frequencies for FM 50MHz? i.e. what rocks to
choose?

2) In order to hear the 6M band I have built a converter to connect
to my Kenwood R5000. I have tried to make a dipole but have no usable
signals yet --- i think a higher antenna is called for. Has anyone any
experience with the 50MHz to 28MHz converter a la Cirkit?

Comments from a "Stateside distributor", who has had experience both ways ...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in existance. However, you can find real bargains in Hong Kong on things that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me know if the view is still as grand as it was on Christmas Day of 1972 ... and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the above, I speak for the Amateur Radio community in general, and I think that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and it is not worth the hassling of dealing with the salesmen over there (prices are not fixed and you have to deal, yes as in bargaining!). Also there is the problem of the warranty. I don't think any of the major brands (K,I,Y) honor warranties of any equipment bought overseas. What I have bought though are accessories. Bring your AES catalog to check the price differences. Some things are cheaper there but others are around the same or even higher depending on the store. Another suggestion is to get away from the Nathan Rd. stores, those are usually overpriced.

Have fun in HK.

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so

the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Subject: Changing Uniden mic wiring?

In article <Pine.CVX.3.91.951022183204.6724E-100000@gibbs.oit.unc.edu> Dale Castle
<dbcastle@gibbs.oit.unc.edu> writes:
>
> I have a Standard C508A and I just got a Uniden clip-on mic w/
>ear phone jack. When I plug it in, it keys the radio. The PTT button
>doesn't stop it. The mic sounds great. Can I change the wiring to make it
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:

```
-------------------------x----------------> TIP
| |
| / 2.2k Radio
(M) \
| / __
|------------------------x----o o--------> RING
PTT
```

The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

>used a 1/2 watt. According to a an article on LEDs, I was supposed to use
>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit

current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

>

> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"
burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control
> Symposium paper. I am trying to contribute to homebrewing by saving
> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph

exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half

wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

When I was in college, I had a vacuum tube operated FM clock radio.
I discovered that the LO radiation on it was so bad that it would
wipe out radios in my dorm room or next door if it was tuned 10.7
MHz. lower in frequency. I had lots of fun silencing my roommates'
(and neighbor's) radios when they listened to music I didn't like.
They never figured out what hit them!

Subject: Want to filter out stupid radio station

I posted before about jamming a radio station. I wasn't that
serious. I just wanted to express my intense dislike of "young"
country. (I won't call it music, that'd be giving it too much credit.)
I have since gotten advice to ask about how to filter out the hated
station or to get a "more selective receiver". Now does anyone have any
more information on these perfectly legal solutions?

You know, I'd like to find one of those too. When I was first
starting out in electronics (we won't go into how many decades ago
that was), I had a simple little cam driven coil winder that was a
lot of fun. Don't know what happened to it, but would love to find
something similar at a hamfest or something.....

I would like to add to this thread - I was there not too long ago and I
got the feeling many stores were more "communications" stores. They had ham,
two way, commercial HF, you name it. Whatever you wanted, whoever you were,
they were happy to sell it to you. Perfectly legal, of course, as it would be
in the US, as long as you didn't try to use it here, or in HK. I suspect the
HK government keeps after toursts trying out their new toys before they leave!

I also found the HK shop keeper's to be the nastiest, most disinterested,
discourteous S.O.B.'s I have EVER run into. It was so bad I asked my hotel
manager what I was doing wrong. He said "probably nothing", adding "being
Caucasian and wanting less than 10 of anything was not a good combination for
many sales people; a serious problem in HK". All of this right after visiting
Tokyo where the HAM (REAL ham) stores where SO polite and friendly I literally
could not believe it.

Dave, WE6L/ Phoenix

From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

Subject: 50MHz transmitter frequencies for UK

I have recently passed my RAE and instead of lashing out on expensive
equipment ,I am going to do some homebrew QRP projects together with
appropriate instrumentation -- see Practical Transmitters for
Novices. What I should like to know:

1) What are best channel frequencies for FM 50MHz? i.e. what rocks to choose?

2) In order to hear the 6M band I have built a converter to connect to my Kenwood R5000. I have tried to make a dipole but have no usable signals yet --- i think a higher antenna is called for. Has anyone any experience with the 50MHz to 28MHz converter a la Cirkit?

: you
: >advise me about:

: I'd save myselft the trouble and buy from a stateside distributor,

Comments from a "Stateside distributor", who has had experience both ways ...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in

existance. However, you can find real bargains in Hong Kong on things
that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me
know if the view is still as grand as it was on Christmas Day of 1972 ...
and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the
above, I speak for the Amateur Radio community in general, and I think
that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and
it is not worth the hassling of dealing with the salesmen over there
(prices are not fixed and you have to deal, yes as in bargaining!).
Also there is the problem of the warranty. I don't think any of the
major brands (K,I,Y) honor warranties of any equipment bought
overseas. What I have bought though are accessories. Bring your AES
catalog to check the price differences. Some things are cheaper there
but others are around the same or even higher depending on the store.
Another suggestion is to get away from the Nathan Rd. stores, those
are usually overpriced.

Have fun in HK.

> ka8ddz, Rochester MI

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.
Ian

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better

since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

Subject: Anybody used Ramsey FX-440 for 9600?.Humm...

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would

make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so
the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Subject: Changing Uniden mic wiring?

In article <Pine.CVX.3.91.951022183204.6724E-100000@gibbs.oit.unc.edu> Dale Castle
<dbcastle@gibbs.oit.unc.edu> writes:
>
> I have a Standard C508A and I just got a Uniden clip-on mic w/
>ear phone jack. When I plug it in, it keys the radio. The PTT button
>doesn't stop it. The mic sounds great. Can I change the wiring to make it
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:

------------------------x----------------> TIP
| |

```
| / 2.2k Radio
(M) \
| / __
|------------------------x----o o--------> RING
PTT
```

The mike (M) is actually a FET buffered electret powered from voltage supplied by the radio. When you close PTT, the mike becomes powered and the TIP voltage is pulled down by the resistor. The voltage drop is sensed in the radio and causes it to go into transmit. The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom standard). The Yaesu mikes work on either rig, though the audio level will be a bit low on an Icom, but the Icom mikes won't always key a Yaesu because they don't sink enough current. My C508A, and most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since the audio sounds good, try just rewiring it so the PTT switch is in series with the ground lead.

>used a 1/2 watt. According to a an article on LEDs, I was supposed to use
>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

>out. The current to the LED is not so critical but what you could use
>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

>prior posting 5 minutes ago caused any problems.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit
current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

> >Hugh Duff VA3TO Toronto

>
> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"
burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control
> Symposium paper. I am trying to contribute to homebrewing by saving
> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph
exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the
distant station. That would certainly help make sure you have enough
signal. If the difference in directions to the two stations is near
90 degrees you will pick up some additional reduction in signal strength
of the offending station due to reduced pickup off the side of the
beam. If you ever looked at pictures of antenna patterns in the ARRL
Handbook, you'll see that large antennas have maximum pickup in the
desired (forward) direction and lots of sharp little points of pickup in
the undesired (side and back) directions. Finding a null can give a
20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on
the offending station even if you have to point slightly away from the
desired station. You might be able to see this happen if you disconnect
the antenna from the receiver and just place the coax cable near the
terminals as you turn the antenna. Can't guarantee anything but it
might work. The better way is to use a high value attenuator between
the coax and the radio. Adjust the attenuator for a weak but readable
signal on the receiver meter. Then turn the antenna until the signal
strength meter on the radio shows as low as possible on the offending
station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I
don't think you'll have any luck at all trying to find any standard
filter to reduce a signal only 800 KHz away. The next option is to use
a second antenna pointed at the offending station and mount the antenna
so the signal it brings into the receiver is 180 degrees out of phase
with the first antenna. The closer you can get to exactly opposite
phase, the more signal will be reduced. Have you ever heard the flutter
of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

From: w8jitom@aol.com (W8JI Tom)
Subject: 40m vertical - How to make?

Hi Mortz,
In article <46ggnc$1j8u@info4.rus.uni-stuttgart.de>,
moritz@ipers1.e-technik.uni-stuttgart.de () writes:

>Read a text book, and you find that the 1/4 wave and the 1/2
>wave antennas behave similar over lossy ground, only that the losses are
>less for the latter due to its higher radiation resistance (not to be
>confused with the feed point resistance). There is no fundamental
>difference, as you are trying to make out.
>

I agree with your basic statement. The ground actually serves the antenna
in two very different ways.

One way is to provide something to "push" the antenna against. The ground
is the other terminal of the antenna, and the current forced into the base

of the antenna causes direct I^2R losses in the ground connection. Raising the *base* or feedpoint impedance helps this problem, but we have to be careful not to fool ourselves by ignoring all the current flowing in the ground connection.

Raising the radiation resistance is not important to these losses, but lowering the total current flow into the ground is. Referring to radiation resistance is confusing, since the actual current loop radiation resistance of a 1/4 wl monopole is only a slight amount lower than the current loop radiation resistance of a half wave monopole, yet the base loop resistance and net current flow into the ground is vastly different between the two.
A resonant end-fed 1/4 wave has a feedpoint resistance of less than 30 ohms, while the end-fed 1/2 wave typically has a feedpoint resistance of several hundred ohms or more. So the end-fed half wave vertical still requires a ground to "push against", although the net current flow from feedpoint is perhaps nearly a hundred times lower than the current from a 1/4 wave element.

I think the confusion comes from "free" or "loose" use of the general term radiation resistance, when they actually are referring to the *base* or *feedpoint* resistance.

The other way the ground interacts is because of field effects causing current flow (and losses) in the earth below the antenna. The half wave has a more concentrated electric field near the earth. The base fed 1/4 wave has a dominate magnetic field near the antenna base. Both 1/4 and 1/2 wave antennas (and all feed systems) certainly require some ground below the antenna if losses are to be minimized. Elevating the entire system a large amount is the only way to effectively "eliminate" this second type of earth loss.

73 Tom

>

I would like to add to this thread - I was there not too long ago and I
got the feeling many stores were more "communications" stores. They had ham,
two way, commercial HF, you name it. Whatever you wanted, whoever you were,
they were happy to sell it to you. Perfectly legal, of course, as it would be
in the US, as long as you didn't try to use it here, or in HK. I suspect the
HK government keeps after toursts trying out their new toys before they leave!

I also found the HK shop keeper's to be the nastiest, most disinterested,
discourteous S.O.B.'s I have EVER run into. It was so bad I asked my hotel
manager what I was doing wrong. He said "probably nothing", adding "being
Caucasian and wanting less than 10 of anything was not a good combination for
many sales people; a serious problem in HK". All of this right after visiting
Tokyo where the HAM (REAL ham) stores where SO polite and friendly I literally
could not believe it.

Dave, WE6L/ Phoenix

From: ab419@freenet.toronto.on.ca (Randie Kochals)
Subject: 4CX1000 Prices?

I am looking around for an Eimac 4CX1000a tube and was wondering
what the going price should be for new and used. If any of you
have seen for sale, or have recently bought one of these, let me
know what I should be prepared to pay.

Thanks

From: daveb@buffnet.net (dave)
Subject: Need Postscript to HP-GL Translator .. Suggestions ?

Greetings,

In need of a translator that will convert poscript files to HP - GL (Laserjet 4L).
I'm hoping that someone knows of a freeware/shareware version that will do
the job.

Thanks

daveb@buffnet.net

From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

Subject: 50MHz transmitter frequencies for UK

I have recently passed my RAE and instead of lashing out on expensive
equipment ,I am going to do some homebrew QRP projects together with
appropriate instrumentation -- see Practical Transmitters for
Novices. What I should like to know:

1) What are best channel frequencies for FM 50MHz? i.e. what rocks to
choose?

2) In order to hear the 6M band I have built a converter to connect
to my Kenwood R5000. I have tried to make a dipole but have no usable
signals yet --- i think a higher antenna is called for. Has anyone any
experience with the 50MHz to 28MHz converter a la Cirkit?

Comments from a "Stateside distributor", who has had experience both ways
...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in existance. However, you can find real bargains in Hong Kong on things that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me know if the view is still as grand as it was on Christmas Day of 1972 ... and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the above, I speak for the Amateur Radio community in general, and I think that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and it is not worth the hassling of dealing with the salesmen over there (prices are not fixed and you have to deal, yes as in bargaining!). Also there is the problem of the warranty. I don't think any of the major brands (K,I,Y) honor warranties of any equipment bought overseas. What I have bought though are accessories. Bring your AES catalog to check the price differences. Some things are cheaper there but others are around the same or even higher depending on the store. Another suggestion is to get away from the Nathan Rd. stores, those are usually overpriced.

Have fun in HK.

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

Subject: Anybody used Ramsey FX-440 for 9600?.Humm...

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so

the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Subject: Changing Uniden mic wiring?

In article <Pine.CVX.3.91.951022183204.6724E-100000@gibbs.oit.unc.edu> Dale Castle
<dbcastle@gibbs.oit.unc.edu> writes:
>
> I have a Standard C508A and I just got a Uniden clip-on mic w/
>ear phone jack. When I plug it in, it keys the radio. The PTT button
>doesn't stop it. The mic sounds great. Can I change the wiring to make it
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:

```
-------------------------x----------------> TIP
| |
| / 2.2k Radio
(M) \
| / __
|------------------------x----o o--------> RING
PTT
```

The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

>used a 1/2 watt. According to a an article on LEDs, I was supposed to use
>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

>out. The current to the LED is not so critical but what you could use
>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit

current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

Gary

The radio remains intact...I just inject the VCO signal further up the
line.
Hmmm... the '157 I have here is running at 26 Mhz !!

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

>
> >You might want to brush up on your personability skills...

>
> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"
burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control

> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph

exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half

wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

Nitpick mode ON:

20 dB is a 100:1 power reduction. 10 dB is 10:1.

Subject: Want to filter out stupid radio station

I posted before about jamming a radio station. I wasn't that
serious. I just wanted to express my intense dislike of "young"
country. (I won't call it music, that'd be giving it too much credit.)
I have since gotten advice to ask about how to filter out the hated
station or to get a "more selective receiver". Now does anyone have any
more information on these perfectly legal solutions?
Stan Kwong

You know, I'd like to find one of those too. When I was first
starting out in electronics (we won't go into how many decades ago
that was), I had a simple little cam driven coil winder that was a
lot of fun. Don't know what happened to it, but would love to find
something similar at a hamfest or something.....

From: w8jitom@aol.com (W8JI Tom)
Subject: 40m vertical - How to make?

Hi Mortz,
In article <46ggnc$1j8u@info4.rus.uni-stuttgart.de>,
moritz@ipers1.e-technik.uni-stuttgart.de () writes:

>Read a text book, and you find that the 1/4 wave and the 1/2
>wave antennas behave similar over lossy ground, only that the losses are
>less for the latter due to its higher radiation resistance (not to be
>confused with the feed point resistance). There is no fundamental
>difference, as you are trying to make out.
>

I agree with your basic statement. The ground actually serves the antenna
in two very different ways.

One way is to provide something to "push" the antenna against. The ground
is the other terminal of the antenna, and the current forced into the base
of the antenna causes direct I^2R losses in the ground connection. Raising
the *base* or feedpoint impedance helps this problem, but we have to be
careful not to fool ourselves by ignoring all the current flowing in the
ground connection.

Raising the radiation resistance is not important to these losses, but
lowering the total current flow into the ground is. Referring to radiation
resistance is confusing, since the actual current loop radiation
resistance of a 1/4 wl monopole is only a slight amount lower than the
current loop radiation resistance of a half wave monopole, yet the base
loop resistance and net current flow into the ground is vastly different
between the two.
A resonant end-fed 1/4 wave has a feedpoint resistance of less than 30
ohms, while the end-fed 1/2 wave typically has a feedpoint resistance of
several hundred ohms or more. So the end-fed half wave vertical still
requires a ground to "push against", although the net current flow from
feedpoint is perhaps nearly a hundred times lower than the current from a
1/4 wave element.

I think the confusion comes from "free" or "loose" use of the general term
radiation resistance, when they actually are referring to the *base* or
feedpoint resistance.

The other way the ground interacts is because of field effects causing
current flow (and losses) in the earth below the antenna. The half wave
has a more concentrated electric field near the earth. The base fed 1/4

wave has a dominate magnetic field near the antenna base. Both 1/4 and 1/2
wave antennas (and all feed systems) certainly require some ground below
the antenna if losses are to be minimized. Elevating the entire system a
large amount is the only way to effectively "eliminate" this second type
of earth loss.

73 Tom

>

I would like to add to this thread - I was there not too long ago and I
got the feeling many stores were more "communications" stores. They had ham,
two way, commercial HF, you name it. Whatever you wanted, whoever you were,
they were happy to sell it to you. Perfectly legal, of course, as it would be
in the US, as long as you didn't try to use it here, or in HK. I suspect the
HK government keeps after toursts trying out their new toys before they leave!

I also found the HK shop keeper's to be the nastiest, most disinterested,
discourteous S.O.B.'s I have EVER run into. It was so bad I asked my hotel
manager what I was doing wrong. He said "probably nothing", adding "being
Caucasian and wanting less than 10 of anything was not a good combination for
many sales people; a serious problem in HK". All of this right after visiting
Tokyo where the HAM (REAL ham) stores where SO polite and friendly I literally
could not believe it.

From: ab419@freenet.toronto.on.ca (Randie Kochals)
Subject: 4CX1000 Prices?

I am looking around for an Eimac 4CX1000a tube and was wondering
what the going price should be for new and used. If any of you
have seen for sale, or have recently bought one of these, let me
know what I should be prepared to pay.

Thanks

Subject: Need Postscript to HP-GL Translator .. Suggestions ?

Greetings,

In need of a translator that will convert poscript files to HP - GL (Laserjet 4L).
I'm hoping that someone knows of a freeware/shareware version that will do
the job.

Thanks

Date: Mon, 23 Oct 1995 21:06:12 GMT
From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

From: giles@wormwood.demon.co.uk (giles)
Subject: 50MHz transmitter frequencies for UK

I have recently passed my RAE and instead of lashing out on expensive equipment ,I am going to do some homebrew QRP projects together with appropriate instrumentation -- see Practical Transmitters for Novices. What I should like to know:

1) What are best channel frequencies for FM 50MHz? i.e. what rocks to choose?

2) In order to hear the 6M band I have built a converter to connect to my Kenwood R5000. I have tried to make a dipole but have no usable signals yet --- i think a higher antenna is called for. Has anyone any experience with the 50MHz to 28MHz converter a la Cirkit?

From: ad7k@bighorn.accessnv.com (Squeak Porray)
Subject: an HT from Hong Kong?

If you want my name just ask. (timhynde@ix.netcom.com) wrote:

: >to Hong Kong soon and am interested in shopping for an HT. What can
: you
: >advise me about:

: I'd save myselft the trouble and buy from a stateside distributor,

Comments from a "Stateside distributor", who has had experience both ways ...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in existance. However, you can find real bargains in Hong Kong on things that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me know if the view is still as grand as it was on Christmas Day of 1972 ... and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the above, I speak for the Amateur Radio community in general, and I think that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and it is not worth the hassling of dealing with the salesmen over there (prices are not fixed and you have to deal, yes as in bargaining!). Also there is the problem of the warranty. I don't think any of the major brands (K,I,Y) honor warranties of any equipment bought

overseas. What I have bought though are accessories. Bring your AES
catalog to check the price differences. Some things are cheaper there
but others are around the same or even higher depending on the store.
Another suggestion is to get away from the Nathan Rd. stores, those
are usually overpriced.

Have fun in HK.

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so
the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Subject: Changing Uniden mic wiring?

In article <Pine.CVX.3.91.951022183204.6724E-100000@gibbs.oit.unc.edu> Dale Castle
<dbcastle@gibbs.oit.unc.edu> writes:
>

> I have a Standard C508A and I just got a Uniden clip-on mic w/
>ear phone jack. When I plug it in, it keys the radio. The PTT button
>doesn't stop it. The mic sounds great. Can I change the wiring to make it
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:

```
-------------------------x----------------> TIP
| |
| / 2.2k Radio
(M) \
| / __
|-------------------------x----o o--------> RING
PTT
```

The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

>used a 1/2 watt. According to a an article on LEDs, I was supposed to use
>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

>out. The current to the LED is not so critical but what you could use
>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit
current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"

burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control
> Symposium paper. I am trying to contribute to homebrewing by saving
> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph
exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending

station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

Balanced feed microphones are outputed by an internal transformer
with an impedance of 150 ohms (nominal). A separate ground shield
that also connects to the mike case, makes the third connection.
For matching reasons, (and certainly for RF shielding also), use
an XLR (the type of connector usually used for balanced mikes) to
Unbalanced in-line transformer. As mentioned, R/S does have one
available. Some low impedance balanced mikes , included some
R/S have offered, alllow an internal connection to provide for
an unbalanced output, but this may not be the proper impedance
for your use.

> done in the broadcast field.
>

In the Amateur Radio field, chances are very very high that operating during a direct strike will more or less kill you, along with all your equipment, regardless of the protection you have invested in. Even if you have 4 or so 8' copper rods pounded into the ground, lightning arrestors or gaps that are connected to the rods through HYDRO wire, etc.

Don't operate your station during a severe lightning storm. Disconnect all your radio equipment including other equipment in the vicinity of your radio equipment. By disconnect, I mean UNPLUG power cables from the mains, and UNPLUG antenna cables. You can go further and ground the termination of the antenna cable.

Even a good ground system will not protect you from a direct strike, cause all you need is a little trickle past the system to do the damage.

I'm not kidding...

4879. Re: '95 Handbook problem (problem solved)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-24 00:00:00 UTC
From: psoper@encore.com
Message-ID: <DGyK6D.Dxy@encore.com>
Source record: 110040

Yesterday I wrote about a problem with making a program for low pass
filter design. I thought there was an error in one of the equations I
based the program on. Email from SABINW@CRPL.CEDAR-RAPIDS.LIB.IA.US
indicates the Handbook equations came from "ITT Handbook", page 10-3,
6th ed 1975 and are accurately copied in the ARRL Handbook. This
gentleperson also had no problem with the example values using "Mathcad"
except that the calculated values don't actually match the Handbook example
(but they are close). My results for all but R1 matched SABIN's exactly.

But here's what the problem is. Some of you folks familiar with floating
point implementations on computers may get a chuckle out of this.

The subexpression with the problem looks like this:

sqrt((X * C2 ^2) - Y)

That is, the square root of X times C2 squared minus Y. The squaring of
C2 is done by multiplying it by itself, not with a power function. This gave
me a domain error because a negative value was being presented to the
computer's square root function. After reading SABIN's mail, I went back
for one more look at my program and by chance futzing rewrote the expression
like this:

sqrt((X * C2 * C2) - Y)

This works! You readers used to perfect math implementations might be pretty
annoyed to find that "X * (C2*C2)" is not the same as "X * C2 * C2" on a
computer. But the float hardware I'm using does produce a *very very small*
difference in results. This tiny difference means that in the OK
case the product comes out to the same value as Y and so the square root gets a
zero argument. In the failing case it gets a very, very small negative value as
an argument because the product is larger than Y.

So no need to bother the ARRL about this one and I can get on with what it was
I was doing to start with.

Regards,
Pete

Hello fellow electronics enthusiasts!

Being an engineer at Ramsey Electronics has put me in an exiting position to bring fun to build and use electronic kits to electronic hobbyists such as myself. Can you believe that I am performing a job that is my hobby as well? (Amazing!) Well, because kit building is my hobby, it turns out that in creating them, we come up with some really cool ideas for products that we would like to build ourselves. My newest, and Ramsey's latest is the Weather Satellite Receiver system. Yes, there are other satellite receivers out there, but how many are kits?

After virtually a year of work on the hardware and the software, I am proud to present an easy to use APT (automatic picture transmission) satellite system. Much work has gone into creating an easy to build electronic kit with clear and concise directions of putting it together, as well as a simple to use and understand graphical interface on the software. We have decided to remove most of the "bells and whistles" out of the program to make it easier for students and inexperienced computer users to learn and use.

Ramsey Electronics is now offering this kit which includes five major parts as follows:

1. Weather satellite antenna - A simple to assemble turnstile antenna system for receiving satellites from horizon to horizon.

2. Antenna Pre-amplifier - A mast mounted RF-Amplifier designed especially for the purpose of weather satellite transmissions. It is powered remotely from the Weather Satellite Receiver through the transmission line.

3. Weather satellite receiver (WSR-1A) - A wide band FM receiver operating around 137.5MHz.

4. Weather satellite decoder board (SD-24) - A "Smart Card" PC interface board that digitizes the signal from the WSR-1A at a very accurate sample rate.

5. Imaging Software (Weather Viewer) - A graphical program written exclusively for the weather satellite systems. It combines the commands most commonly used for satellite image enhancement into one package.

For more information on this subject e-mail me at the following address, and I will send you some technical information and also a sample image taken from a tape recording. This image will demonstrate

how well the satellite decoder card locks onto and aligns the satellite signals.

Yours sincerely;

Mark Wyman

: anymore. Thanks N1AEP

You could use an output transformer for a tube audio amp, and feed it
backwards" with a low impedance solid state audio amp. Make sure
that the one you find can deal with the DC current needed. Most high
powered audio amp output transformers would be push pull and in their
normal operation the DC would balance out.

Or you could use the autotransformer trick used in the 160 meter rig in
the 1968 ARRL handbook. This is where you only use the primary of an
output transformer. One side goes to the final's power, the other side
to a single ended audio output, and the power goes to the center tap.

Or you could try winding your own. Try finding "Practical Transformer
Design Handbook" by Lowdon.

Or you could skip the transformer. Some of the later tube AM broadcast
band transmitters use a cathode follower modulation stage totem poled on
top of the final. (In that case, power dissipation is kept down by
driving the audio stage with a 70 kHz pulse width modulated signal.
Some serious filtering is needed between this stage and the RF final.)

Or use screen grid modulation.

From: ab419@freenet.toronto.on.ca (Randie Kochals)
Subject: 4CX1000 Prices?

I am looking around for an Eimac 4CX1000a tube and was wondering
what the going price should be for new and used. If any of you
have seen for sale, or have recently bought one of these, let me
know what I should be prepared to pay.

Thanks

Subject: Need Postscript to HP-GL Translator .. Suggestions ?

Greetings,

In need of a translator that will convert poscript files to HP - GL (Laserjet 4L).
I'm hoping that someone knows of a freeware/shareware version that will do
the job.

Thanks

From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

Subject: 50MHz transmitter frequencies for UK

I have recently passed my RAE and instead of lashing out on expensive
equipment ,I am going to do some homebrew QRP projects together with
appropriate instrumentation -- see Practical Transmitters for
Novices. What I should like to know:

1) What are best channel frequencies for FM 50MHz? i.e. what rocks to
choose?

2) In order to hear the 6M band I have built a converter to connect
to my Kenwood R5000. I have tried to make a dipole but have no usable
signals yet --- i think a higher antenna is called for. Has anyone any
experience with the 50MHz to 28MHz converter a la Cirkit?

: you

: >advise me about:

: I'd save myselft the trouble and buy from a stateside distributor,

Comments from a "Stateside distributor", who has had experience both ways ...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in existance. However, you can find real bargains in Hong Kong on things that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me know if the view is still as grand as it was on Christmas Day of 1972 ... and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the above, I speak for the Amateur Radio community in general, and I think that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and it is not worth the hassling of dealing with the salesmen over there (prices are not fixed and you have to deal, yes as in bargaining!). Also there is the problem of the warranty. I don't think any of the major brands (K,I,Y) honor warranties of any equipment bought overseas. What I have bought though are accessories. Bring your AES catalog to check the price differences. Some things are cheaper there but others are around the same or even higher depending on the store. Another suggestion is to get away from the Nathan Rd. stores, those are usually overpriced.

Have fun in HK.

> ka8ddz, Rochester MI

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.
Ian

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

Subject: Anybody used Ramsey FX-440 for 9600?.Humm...

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so

the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Subject: Changing Uniden mic wiring?

In article <Pine.CVX.3.91.951022183204.6724E-100000@gibbs.oit.unc.edu> Dale Castle
<dbcastle@gibbs.oit.unc.edu> writes:
>
> I have a Standard C508A and I just got a Uniden clip-on mic w/
>ear phone jack. When I plug it in, it keys the radio. The PTT button
>doesn't stop it. The mic sounds great. Can I change the wiring to make it
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:

```
-------------------------x----------------> TIP
| |
| / 2.2k Radio
(M) \
| / __
|------------------------x----o o--------> RING
PTT
```

The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

Subject: Ladder Line .. how to make?

Ron and Drew...

.. I remember seeing ladder line where the spacers were made from old
BIC byros (body), if you are going for 2" spacing then a each byro will provide
2 spacers (or a byro per 4' of line - roughly).

Just might save you a bit of sawing... rest of the method the same.

>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

>out. The current to the LED is not so critical but what you could use
>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

>prior posting 5 minutes ago caused any problems.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit

current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

>

> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"
burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control
> Symposium paper. I am trying to contribute to homebrewing by saving
> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph

exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half

wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

Date: Mon, 23 Oct 1995 21:06:12 GMT
From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

Subject: 50MHz transmitter frequencies for UK

I have recently passed my RAE and instead of lashing out on expensive equipment ,I am going to do some homebrew QRP projects together with appropriate instrumentation -- see Practical Transmitters for Novices. What I should like to know:

1) What are best channel frequencies for FM 50MHz? i.e. what rocks to choose?

2) In order to hear the 6M band I have built a converter to connect to my Kenwood R5000. I have tried to make a dipole but have no usable signals yet --- i think a higher antenna is called for. Has anyone any experience with the 50MHz to 28MHz converter a la Cirkit?

: you
: >advise me about:

: I'd save myselft the trouble and buy from a stateside distributor,

Comments from a "Stateside distributor", who has had experience both ways ...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the

radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in existance. However, you can find real bargains in Hong Kong on things that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me know if the view is still as grand as it was on Christmas Day of 1972 ... and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the above, I speak for the Amateur Radio community in general, and I think that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and
it is not worth the hassling of dealing with the salesmen over there
(prices are not fixed and you have to deal, yes as in bargaining!).
Also there is the problem of the warranty. I don't think any of the
major brands (K,I,Y) honor warranties of any equipment bought
overseas. What I have bought though are accessories. Bring your AES
catalog to check the price differences. Some things are cheaper there
but others are around the same or even higher depending on the store.
Another suggestion is to get away from the Nathan Rd. stores, those
are usually overpriced.

Have fun in HK.

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.
Ian

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

Subject: Anybody used Ramsey FX-440 for 9600?.Humm...

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so
the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Subject: Changing Uniden mic wiring?

In article <Pine.CVX.3.91.951022183204.6724E-100000@gibbs.oit.unc.edu> Dale Castle
<dbcastle@gibbs.oit.unc.edu> writes:
>
> I have a Standard C508A and I just got a Uniden clip-on mic w/
>ear phone jack. When I plug it in, it keys the radio. The PTT button
>doesn't stop it. The mic sounds great. Can I change the wiring to make it
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:

```
-------------------------x----------------> TIP
| |
| / 2.2k Radio
(M) \
| / __
|------------------------x----o o--------> RING
PTT
```

The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

>used a 1/2 watt. According to a an article on LEDs, I was supposed to use
>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

>out. The current to the LED is not so critical but what you could use
>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

>prior posting 5 minutes ago caused any problems.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit
current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

> >don't contribute positively to the spirit of homebrewing !
> >
> >Hugh Duff VA3TO Toronto

>
> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"

burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control
> Symposium paper. I am trying to contribute to homebrewing by saving
> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph
exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending

station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

Nitpick mode ON:

20 dB is a 100:1 power reduction. 10 dB is 10:1.

>

When I was in college, I had a vacuum tube operated FM clock radio.
I discovered that the LO radiation on it was so bad that it would
wipe out radios in my dorm room or next door if it was tuned 10.7
MHz. lower in frequency. I had lots of fun silencing my roommates'
(and neighbor's) radios when they listened to music I didn't like.
They never figured out what hit them!

Subject: Want to filter out stupid radio station

I posted before about jamming a radio station. I wasn't that
serious. I just wanted to express my intense dislike of "young"
country. (I won't call it music, that'd be giving it too much credit.)
I have since gotten advice to ask about how to filter out the hated
station or to get a "more selective receiver". Now does anyone have any
more information on these perfectly legal solutions?
Stan Kwong

You know, I'd like to find one of those too. When I was first
starting out in electronics (we won't go into how many decades ago
that was), I had a simple little cam driven coil winder that was a
lot of fun. Don't know what happened to it, but would love to find
something similar at a hamfest or something.....

Greetings,

In need of a translator that will convert poscript files to HP - GL (Laserjet 4L).
I'm hoping that someone knows of a freeware/shareware version that will do
the job.

Thanks

From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

Subject: 50MHz transmitter frequencies for UK

I have recently passed my RAE and instead of lashing out on expensive
equipment ,I am going to do some homebrew QRP projects together with
appropriate instrumentation -- see Practical Transmitters for
Novices. What I should like to know:

1) What are best channel frequencies for FM 50MHz? i.e. what rocks to
choose?

2) In order to hear the 6M band I have built a converter to connect
to my Kenwood R5000. I have tried to make a dipole but have no usable
signals yet --- i think a higher antenna is called for. Has anyone any
experience with the 50MHz to 28MHz converter a la Cirkit?

: you
: >advise me about:

: I'd save myselft the trouble and buy from a stateside distributor,

Comments from a "Stateside distributor", who has had experience both ways
...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in existance. However, you can find real bargains in Hong Kong on things that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me know if the view is still as grand as it was on Christmas Day of 1972 ... and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the above, I speak for the Amateur Radio community in general, and I think that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and it is not worth the hassling of dealing with the salesmen over there (prices are not fixed and you have to deal, yes as in bargaining!). Also there is the problem of the warranty. I don't think any of the major brands (K,I,Y) honor warranties of any equipment bought overseas. What I have bought though are accessories. Bring your AES catalog to check the price differences. Some things are cheaper there but others are around the same or even higher depending on the store. Another suggestion is to get away from the Nathan Rd. stores, those are usually overpriced.

Have fun in HK.

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.
Ian

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

Subject: Anybody used Ramsey FX-440 for 9600?.Humm...

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so

the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Subject: Changing Uniden mic wiring?

In article <Pine.CVX.3.91.951022183204.6724E-100000@gibbs.oit.unc.edu> Dale Castle
<dbcastle@gibbs.oit.unc.edu> writes:
>
> I have a Standard C508A and I just got a Uniden clip-on mic w/
>ear phone jack. When I plug it in, it keys the radio. The PTT button
>doesn't stop it. The mic sounds great. Can I change the wiring to make it
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:

```
-------------------------x----------------> TIP
| |
| / 2.2k Radio
(M) \
| / __
|------------------------x----o o--------> RING
PTT
```

The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

Gary

>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit

current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

>
> >You might want to brush up on your personability skills...

> >
> >Hugh Duff VA3TO Toronto

>
> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"
burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control

> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph

exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half

wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

From: ab419@freenet.toronto.on.ca (Randie Kochals)
Subject: 4CX1000 Prices?

I am looking around for an Eimac 4CX1000a tube and was wondering
what the going price should be for new and used. If any of you
have seen for sale, or have recently bought one of these, let me
know what I should be prepared to pay.

Thanks

Subject: Need Postscript to HP-GL Translator .. Suggestions ?

Greetings,

In need of a translator that will convert poscript files to HP - GL (Laserjet 4L).
I'm hoping that someone knows of a freeware/shareware version that will do
the job.

Thanks

From: psoper@encore.com (Pete Soper)
Subject: '95 Handbook problem, need email or phone reference

Hi folks,
I've plugged a lot of numbers into the R1 resistor equation of
the low-pass active filter design description in figure 16.54 on page
16.30 of the '95 "ARRL Handbook". I'm convinced that either the
equation is in error or I've lost my mind. In case it's the former problem
(or to get quickly to the latter), could somebody recommend how I can pursue
this with the ARRL? Is there a department to ask for on the phone (#?)
or an email address for this kind of query?
Please send me email direct if you can help, as postings to this
group are averaging 7-12 days to ooze through our news feed.
My problem is that the "[a^2 + 4b(K-1)]C2^2" subexpression results
in an attempt to take the square root of a negative value because this comes
out smaller than the "4bC1C2" subexpression subtracted from it. If I guess
that parentheses are missing and it should be written "([a^2 + 4b(K-1)]C2)^2"
I get the wrong result for the example values given. I can't come up with
a second guess :-)

Thanks,
Pete

Subject: 50MHz transmitter frequencies for UK

I have recently passed my RAE and instead of lashing out on expensive equipment ,I am going to do some homebrew QRP projects together with appropriate instrumentation -- see Practical Transmitters for Novices. What I should like to know:

1) What are best channel frequencies for FM 50MHz? i.e. what rocks to choose?

2) In order to hear the 6M band I have built a converter to connect to my Kenwood R5000. I have tried to make a dipole but have no usable signals yet --- i think a higher antenna is called for. Has anyone any experience with the 50MHz to 28MHz converter a la Cirkit?

If you want my name just ask. (timhynde@ix.netcom.com) wrote:

: >to Hong Kong soon and am interested in shopping for an HT. What can
: you
: >advise me about:

: I'd save myselft the trouble and buy from a stateside distributor,

Comments from a "Stateside distributor", who has had experience both ways ...

If you buy a radio from someone you never saw before, and never expect to see again, all he is going to be interested in is getting your money out of your wallet and you on your way.

If you buy from a local (or regional) dealer, you are buying from someone who wants to see YOU happy, since he hopes that you will come back again and again, for all those accessories, mobile radios, antennas and the like that we hams always need to add to our collection.

If you bring in an oversees "Yaekenicostanco" radio, you will have NO US warranty - the American distributors warrant only those radios that they import, and quite possibly might not service them - they are completely within their rights to do so. There very well may be (as has been in the past) board or component differences between various versions of the

radio destined for different countries, thus compounding the situation. (Some manufacturers have had up to five different versions of the same radio - with each version destined for a different market area, with different regulations.)

If you buy the radio from a local (or regional) dealer, you have someone you can go to with questions and problems ... but long-distance calls to Hong Kong to get answers to a question get expensive - to say nothing of "how do you ask someone how to program odd splits for repeaters into your new handy - when he is only really fluent, technically, in Chinese?"

I doubt that you will find any significant price differentials in buying in Hong Kong ... that was true years ago (I was there during the VietNam era), but not now, with the global economy/distribution situation now in existance. However, you can find real bargains in Hong Kong on things that are local-labor-intensive (like tailored suits for example).

Enjoy your trip ... take the tram to the top of Victoria Peak and let me know if the view is still as grand as it was on Christmas Day of 1972 ... and good luck to you!

Very 73,

"Squeak" Porray, AD7K
Manager, Amateur Electronic Supply/Las Vegas

ps: I hope you don't think I am touting just our company ... in the above, I speak for the Amateur Radio community in general, and I think that it speaks for all domestic Amateur Radio Dealers as well.

I agree with Tim. I've been to HK several times on business trips and
it is not worth the hassling of dealing with the salesmen over there
(prices are not fixed and you have to deal, yes as in bargaining!).
Also there is the problem of the warranty. I don't think any of the
major brands (K,I,Y) honor warranties of any equipment bought
overseas. What I have bought though are accessories. Bring your AES
catalog to check the price differences. Some things are cheaper there
but others are around the same or even higher depending on the store.
Another suggestion is to get away from the Nathan Rd. stores, those
are usually overpriced.

Have fun in HK.

Tim,
Many years ago, I built a six-channel radio on 6M using a design
published as a series of articles by Radio Control Modeller (RCM)
magazine. If you can find some older issues circa 1970 or contact
RCM, they may be able to send you the information.

The radio is still running in a Soling 1M yacht that I race occasionally
at our yacht club.

Good luck.

Sure, lossy *Earth* near an antenna is always a problem, so keep
your antennas well away from Earth, but that doesn't address his
comment. A halfwave antenna *does not require ground* to function.
It doesn't need it to act as a current mirror the way a quarterwave
does. A halfwave vertical is perfectly content to function properly
in *free space*. A quarterwave needs some sort of counterpoise.
That counterpoise *can* be Earth, but it doesn't have to be. Radials,
or a counterpoise wire, will work just as well, probably better
since they won't be as lossy as Earth.

Subject: AMSOFT SPAM

Bob:

I stand by my previous comment: SPAM-soft.

The gentlemen (NOT) at AMSOFT wisely chose to send their message to at least
ten newsgroups on this round of their shameless advertising. Regardless
of the value of the information they provide, their relentless SPAMMing
of the amateur radio radio newsgroups is unjustifiable and inexcusable.

There was a major SPAM attack from Amsoft the last time they had a new
CD release. And the time before that. AND the time before THAT! They
have an unfortunate history for alienating a lot of us and for wasting a lot
of bandwidth.

That you would support their activity says something about you -- not sure
what, exactly. But it's not in keeping with newsgroup's non-commercial charter.

If you are reading this, it's because I'm wasting bandwidth only on the
rec.radio.* newsgroup I read. And if you reply to my flaming diatribe,
you will do so only to this newsgroup, unless you choose to add groups.
Of course you understand how to add and remove groups from your To:
field in your newsreader. You DO understand how that works, don't you?

Subject: Anybody used Ramsey FX-440 for 9600?.Humm...

>>Does the Ramsey FX-440 transceiver kit actually work for 9600 baud packet?
>>I have friend-of-a-friend word that Ramsey claims it works on 9600 baud
>>packet, but nobody has actually been able to get it going quite right.

Some time ago I bought their kit. I found that the receiver suffered
from
many spurious responses which, given right (wrong?) packet frequency
would
make it pretty useless. I did get it to receive 9600 but had a pretty
strong signal to work with and didn't make any performance measurements
so
I can't really comment on the receive performance. The transmitter was
a
disaster! Because they have no shielding anywhere in the radio the
transmitter output got back into the PLL and the resultant signal
resembled
broadband noise. I wasted a lot of time trying to clean that up and
never
was successful. I believe that taking the time to build a good shield
around the PLL would have solved the problem but there are problems with
the board layout that make it a difficult thing to do. I did find a
few
minor design errors which resulted a very long (for 9600 packet) TR
turnaround time. They directly modulate the VCO, like most radios, so
the
transmitter will distort the signal. I never got far enough to worry
about
that.

A friend of mine bought one and had similar problems. Both of us wasted
a
good bit of money. Since then we have discovered the joys of converting
commercial (e.g., Motorola and GE) radios...they work!

My recommendation is to avoid the unit unless they have made major
design
changes since the original radio (the 2-m version failed the transmitter
spurious output test -- see the QST review from about a year ago).

Subject: Changing Uniden mic wiring?

In article <Pine.CVX.3.91.951022183204.6724E-100000@gibbs.oit.unc.edu> Dale Castle
<dbcastle@gibbs.oit.unc.edu> writes:
>
> I have a Standard C508A and I just got a Uniden clip-on mic w/
>ear phone jack. When I plug it in, it keys the radio. The PTT button
>doesn't stop it. The mic sounds great. Can I change the wiring to make it
>work? (bought it used.) Thanks in advance for the help.

Dale, the C508A uses the same "leaky PTT" circuit as Icom/Yaesu/Radio Shack.
Mikes wired for those brands will work. I'm not familiar with the Uniden
mike, but here's roughly what the I/Y/RS circuit looks like:

```
-------------------------x----------------> TIP
| |
| / 2.2k Radio
(M) \
| / __
|-------------------------x----o o--------> RING
PTT
```

The mike (M) is actually a FET buffered electret powered from voltage
supplied by the radio. When you close PTT, the mike becomes powered
and the TIP voltage is pulled down by the resistor. The voltage
drop is sensed in the radio and causes it to go into transmit.
The resistor may vary between 2.2k (Yaesu standard) to 10k (Icom
standard). The Yaesu mikes work on either rig, though the audio
level will be a bit low on an Icom, but the Icom mikes won't always
key a Yaesu because they don't sink enough current. My C508A, and
most HTX-202s, don't care, they'll work with either.

It sounds like your Uniden mike uses a different scheme, but since
the audio sounds good, try just rewiring it so the PTT switch is
in series with the ground lead.

>used a 1/2 watt. According to a an article on LEDs, I was supposed to use
>20 milliamps to calculate the resistance and wanted to drop from 50 to 2.
>I am obviously doing something wrong. PLEASE HELP!

Ok, lets do some calculations. The original circuit had a 240 ohm
resistor. For 20 ma of diode current, the voltage feeding the
resistor needs to be

E=0.02*240+1.6 = 6.4 volts

and the resistor power dissipation is

P=.02*4.8 = 0.096 watts

So a half-watt resistor offers a comfortable safety margin.
But if the voltage is 50 volts, then we have a power dissipation
in the resistor of

P=48.4^2/240 = 9.76 watts

A half-watt resistor is going to go *poof*, as it indeed did.
So either the value of the original resistor was *not* 240 ohms,
or the design voltage is *not* 50 volts.

Now you replaced the resistor with a 2500 ohm resistor, so the
power dissipation of that resistor would be

P=48.4^2/2500 = 0.937 watt

A 5 watt resistor would be about right to provide an adequate
safety margin. (You never want to run a resistor at its power
dissipation limit, it'll run about 100 C at that power level.)

But the original resistor was a half-watt unit, indicating a
design dissipation of 1/10th watt or less. Clearly something
is wrong here. I'd suspect it's the 50 volts. Are you *sure*
it's *supposed* to be 50 volts?

>out. The current to the LED is not so critical but what you could use
>a 220 or 270 Ohm 2W resistor.

Better run that calc again. You slipped a decimal. That's *50* volts,
not *5.0* volts he's saying. A 220 to 270 ohm resistor would be
correct for *5.0* volts. You got the power right though, a *2400*
ohm resistor would dissipate about 1 watt (actually 0.976 watt).
And that's too much for a half watt part. Either the voltage is
supposed to be much lower, or there's supposed to be something
else in the circuit acting as a current limiter besides the
240 ohm half watt resistor in there originally.

And my apologies for posting a correction before reading your correction.
We're all singing out of the same hymn book now though. I'm beginning to
suspect a fault in another part of the circuit. Obviously, even if the
original resistor were 2400 ohms and a color band turned when it smoked,
that still doesn't address the fact that it was a *half watt resistor*.
There's got to be something else in the circuit that's supposed to limit
current. *That's* the part that probably failed and took the resistor
with it, and is still causing new resistors to smoke.

The radio remains intact...I just inject the VCO signal further up the
line.
Hmmm... the '157 I have here is running at 26 Mhz !!

Hmmm...mine's working at 26 MHz !!
Maybe this is pushing it to its limit.

In the search for more of these parts we have discovered that it *MAY*
be a discontinued item. We are considering trying out
the MC145190 (if we can get 'em from the supplier). Good to 1.1 GHz
with onboard dual modulus prescalars...surface mount only though :(

>
> Well, sorry, but what you are talking about *is* a simple minded synthesizer.

What is simple minded about a PLL/Loop Filter/VCO when properly
designed ? I didn't intend on building up some half-assed "well, it
kinda works" board. That was the intent of the original post...tell me
what I need to know and/or HELP me design a solid performer !
If you don't want to get involved in a positive way, say nothing !
Perhaps I'm being a bit anal retentive but the net seems to be full
of the "I can tell you you're wrong but I can't tell you how to
do it right" types.

I suggest that your delivery is somewhat abrasive...try having some
compassion for those of us who are attempting to learn. Nothing is more
of a turnoff than having someone who comes off like a "know-it-all"

burst your ballon. Albeit, you may know your stuff *BUT* your delivery
needs some honing.

> If you want to see a sophisticated one, read my 1995 Frequency Control
> Symposium paper. I am trying to contribute to homebrewing by saving
> people from endless frustration. (BTW, another poster suggested a DDS;
> great idea! Far more homebrewable.)
>
> Rick Karlquist N6RK
> rkarlqu@scd.hp.com

The only frustration so far has been the negativity expressed by
yourself. Why you didn't instead say...

Hey man..."I've been there... done that..."
"Why don't you look at this other PLL chip...your '157 is
only rated for XX MHz and may cause you problems with XXX. Your best
approach would be to use the MC145XXX (or whatever). The loop filter is
a key element in the design...it dictates many of the characteristics
of the VCO operation...I can help to get you on your way...what are your
requirements ie.. lock-up time, step size, phase noise ect...?
Hey, I have a great VCO design that works well in the range you
require...let me send you a copy of it !...I think if you follow these
guidelines you'l be headed in the right direction..."
(I'm not quite asking for some expert to hold my hand through the design...
I DO have a bit of a clue what I'm doing but the above paragraph
exhibits somewhat of a kinder approach...more of what I was expecting.)

...is beyond me. Maybe you have a fat head. (It sounds like it...
"If you want to see a sophisticated one, read my...")
Ya, you're cool !

Keep in mind that this newsgroup is the Ham Radio Homebrewing
conference...hobbiests, many of whom are interested to learn,
myself included. If you wanna make love to yourself, do so in private !

From: n0nas@hamlink.mn.org (Doug Reed)
Subject: Unwanted Fm station (1)

to: all
A question was asked by kennedy@aol.com

>>I live in the country. Too bad, right? My favorite FM stereo
>>station is 100 miles away on 102.1 FM. The problem is an
>>FM station 5 miles from my house transmitting 50KW on 101.9 MHz.

One of the other replies suggested a bigger antenna pointed at the distant station. That would certainly help make sure you have enough signal. If the difference in directions to the two stations is near 90 degrees you will pick up some additional reduction in signal strength of the offending station due to reduced pickup off the side of the beam. If you ever looked at pictures of antenna patterns in the ARRL Handbook, you'll see that large antennas have maximum pickup in the desired (forward) direction and lots of sharp little points of pickup in the undesired (side and back) directions. Finding a null can give a 20 dB (1/10th) reduction (or more) in signal strength.

Ideally what you want to do is put one of the side lobe NULLS right on the offending station even if you have to point slightly away from the desired station. You might be able to see this happen if you disconnect the antenna from the receiver and just place the coax cable near the terminals as you turn the antenna. Can't guarantee anything but it might work. The better way is to use a high value attenuator between the coax and the radio. Adjust the attenuator for a weak but readable signal on the receiver meter. Then turn the antenna until the signal strength meter on the radio shows as low as possible on the offending

station. This gets you the LEAST offending signal possible.

Assuming just changing one antenna isn't enough to fix your problem, I don't think you'll have any luck at all trying to find any standard filter to reduce a signal only 800 KHz away. The next option is to use a second antenna pointed at the offending station and mount the antenna so the signal it brings into the receiver is 180 degrees out of phase with the first antenna. The closer you can get to exactly opposite phase, the more signal will be reduced. Have you ever heard the flutter of multipath on a station? That is what we are trying to do here.

The second antenna can be much smaller than the main antenna because the station is so close. This will not be easy because you have to match not only the signal phase to cancel but also the signal strength. Start by using the attenuator with the receiver and first antenna to try getting a known signal level on the offending station. Next connect the second antenna in place of the first and use another attenuator or extra length of coax (100's of feet) or maybe just a resistor short at the antenna until you have reduced the signal strength to match the first antenna.

Once the signal strengths are egual, connect BOTH antennas to the receiver at the same time using a 2 way splitter/combiner. Now you begin moving the second antenna around until the offending signal is at minimum. That is the position for maximum cancelation. How far do you have to move it? Well, figure the wavelength of the signal. A half wave is about 495/frequency so a full wave length would be 2*495/106 = 9.3 feet. So somewhere along a line from the first antenna toward the offending station, within a ten foot distance, you should find a null. This doesn't mean you have to be within 10 feet of the first antenna, just a 10 foot movement somewhere in the direction of the offending station. You probably should keep the second antenna ten feet away from the first antenna just to reduce antenna pattern changes since you just got done carefully pointing the first antenna.

Another method of cancelling the signal is by changing the length of the coax from the second antenna to the receiver, because changing the length is just like moving the antenna. Now, the wavelength in coax is shorter than the wavelength in air. This is called the velocity factor of the coax cable. Most foam coax has a velocity factor of around 80%. This means that 10 feet in air is only 8 feet in the coax. So, somewhere in 8 feet of cable is the exact length you need to cancel the offending station. If you choose this method, all you can do is cut off the cable a little bit at a time until you have minimum signal from the offending station. I've never tried this myself so I don't know how small of cuts you should make so you don't go past the null. I'd just figure you'll start with an extra 20 feet of cable and start cutting maybe 6 inches at a time. I assume you'll be able to hear multipath distortion of the signal as you get closer to the right length and can start making smaller cuts.

It is my understanding that this basic technique is frequently used in commercial broadcast radio where they may have similar problems. I understand they use more of a tuneable (low pass?) filter of some sort to adjust the phase shift instead of cutting the coax. This phase cancellation technique is the only one I've ever heard of that might do you any good. The only other options involve replacing the receiver with something much more expensive, designed for extremely high signal overload and superb IF bandwidth filtering. I've never heard of such a receiver but I'm sure they exist if you have a LOT of money.

I really don't have much hope that anything is going to let you receive your desired station. With 50 KW only 5 miles away, everything in your

>less for the latter due to its higher radiation resistance (not to be
>confused with the feed point resistance). There is no fundamental
>difference, as you are trying to make out.
>

I agree with your basic statement. The ground actually serves the antenna in two very different ways.

One way is to provide something to "push" the antenna against. The ground is the other terminal of the antenna, and the current forced into the base of the antenna causes direct I^2R losses in the ground connection. Raising the *base* or feedpoint impedance helps this problem, but we have to be careful not to fool ourselves by ignoring all the current flowing in the ground connection.

Raising the radiation resistance is not important to these losses, but lowering the total current flow into the ground is. Referring to radiation resistance is confusing, since the actual current loop radiation resistance of a 1/4 wl monopole is only a slight amount lower than the current loop radiation resistance of a half wave monopole, yet the base loop resistance and net current flow into the ground is vastly different between the two.
A resonant end-fed 1/4 wave has a feedpoint resistance of less than 30 ohms, while the end-fed 1/2 wave typically has a feedpoint resistance of several hundred ohms or more. So the end-fed half wave vertical still requires a ground to "push against", although the net current flow from feedpoint is perhaps nearly a hundred times lower than the current from a 1/4 wave element.

I think the confusion comes from "free" or "loose" use of the general term radiation resistance, when they actually are referring to the *base* or *feedpoint* resistance.

The other way the ground interacts is because of field effects causing current flow (and losses) in the earth below the antenna. The half wave has a more concentrated electric field near the earth. The base fed 1/4 wave has a dominate magnetic field near the antenna base. Both 1/4 and 1/2 wave antennas (and all feed systems) certainly require some ground below the antenna if losses are to be minimized. Elevating the entire system a large amount is the only way to effectively "eliminate" this second type

of earth loss.

I've seen quite a few posts on here from time to time from people using the the ISD voice chips availble from Radio Shack and other places. Excuse the advertising here but there is quite a bit of applications information now available on these parts via the World Wide Web.

Information Storage Devices, also know as ISD now has a Web page including quite a bit of applications information. Eventually (I hope in the next few weeks) we will have all our data sheets and the entire Design Manual on line. Currently, however, there are a number of application Briefs that show how to use several of the different parts we make.

Look for the application briefs under http://www.isd.com/apps.html. They are listed on the page . . . just click on what you want to see. The App Briefs include schematics where appropriate. Of course, our home page is http://www.isd.com.

I too have the tm-742a with the 28mhz unit and I am having no problem
Reciving over 30mhz. The only problem I am having is that when I tx on
high power in the 28mhz range It locks up the radio. A friend of mine has
the same radio and the recive is fine but he too has the TX problem. I
would check the mod again and make sure you are following the ARTSCI book
and they will work fine.

Unfortunatly, it's an FM station. It comes in at 105.1 from
about 50 miles away. The station I want, 105.3, is broadcast from
the southeast about 100 miles away BTW, I can't set up any big
directional antennas, I'm a college student and I don't think the owner
of the house I'm renting would like me setting anything up on his roof.
Besides I don't have that much money.
Thanks,
Stan Kwong

If you are still looking for a grid dip meter, MFJ's 1996 catalog showed up yesterday with a 1.5 to 250 MHz dip meter for $120. Its solid state with a built in sine wave modulator.

MFJ: 1-800-647-1800

I haven't tried one myself, I'm still looking for an old classic at the swaps, but if I don't have any luck there I may check this one out.

>Jack WB3U

This is something inherent in the nature of floating point arithmetic.
By definition, precision is limited by the number of bits in the
chosen representation format. Subtracting two numbers that are
"with the noise of" each other is likely to lead to a very small
number one side or the other ("within the noise") of zero. Expecting
to get exactly zero is a bad idea. Expecting the number to stay
strictly positive is a bad idea. Dealing with loss of precision
and accumulation of error is fundamental to writing stable floating
point algorithms, just like a clean LO is fundamental to receiver
performance. It is also just about as arcane, and about as
misunderstood *sigh*.

Here are a few rules to live by:
1) don't test for floating point zero -- do test for a small range
near zero.
2) don't add/subtract a small number with a much larger number.
the small number will be swamped. do re-order your expression
to avoid the situation.
3) remember that subtracting numbers very close to each other creates
very small numbers that lead to instabilities if you later:
a) expect them to stay positive
b) divide by them (the result may go to infinity)
Do guard uses of potentially small numbers with tests for
unsafe conditions.
4) beware transcendental function end-cases (inputs that lead to results
close to infinity or zero). This is another source of instabilities.
Do brush up on your trigonometry

Hope that helps.

To ALL:
I have a TM_742a with the UT-28s module installed. I also have
done the expanded TX/RX on the unit. The unit works fine except on
the 10M side. It seems that the unit can TX up to 45mhz, but it
will not RX over 30mhz. I sent the unit to Kenwood Service Center
East and they said it is up to specs. The problem is that I need
to receive freqs. at 33.94 and lower. I can tranmit there but I
don't need that I just need to receive. These are fire bands and
going to the fire calls without having a scanner in the car would
be a great help.

Is there anyway to fix this problem???
ANY HELP IS GREATLY NEEDED!!!

THanks Robert H&#65533;yvald, KB2UWJ

Hi Allen:

I'm not sure this is what you are after, but Motorola has an impedance matching program that is free. I got a copy directly from them, however unless I'm mistaken (often this is true) the ARRL BBS and mirrors have it. Look for a file named "MINP" (zip, I think). It's a little quirky; be sure to always have a component entered, even if it's a 0 nH inductor, before you do anything else.

Also there was a program called something like "MATCH5" or "RFMATCH5" I believe. Since I have ARRL Radio Designer, MicroSmith and some others, I deleted this one from my drive so I'm working by memory here.

>resisitor connecter to a 50 volt dc source.

KO0B said:>50V in an EQ??? R coulda been 24K.

I agree. way too low of a R and too hi of a voltage for an eq.

Could you have misread the voltage? Decimal point in wrong place?

5vdc and 240 ohms sounds closer!

50v
------- = .208 amps or 208ma pretty high current for an LED.
240 ohms

.208ma * 50v = 10.4 watts High dissipation for a 1/2w resistor.

Perhaps your voltage reg went splat?

Stan,
Well, the only solution that I can think of that would be cost
effective and help solve your problem here is to upgrade your FM receiver
on you own. Find the 10.7 MHz bandpass filter (usually ceramic these
days) and replace it with a 150 KHz BW TOKO model SK107M4-A0-10 (Digi-Key
TK2308-ND). You will notice a loss in fidelity of the desired station,
but a definite reduction in the level of the interfering one. With the
constrictions given (money, landlord), there's few options available.

Source record: 110069

I'll briefly give you my experiences with an elevated feed 40 m ant.
Last year about this time (when people stopped using the yard).
I put up one.
I have a tower with an 80 m. dipole strung over to a tree. I dropped a
1/4 wave 40 m. wire element down from the end of the dipole, put an insulator
on it, attached 4 radials and ran them over to supports about 6 ft.
off the ground. The feed point was about 15 ft high.

Then I compared this wire "ground plane" all winter long with the dipole
right above it (which I feed with bal. line to a tuner).

In 90 % of the cases I couldn't tell a difference.
DX to Europe was just as strong with the dipole (Disappointment).
Domestic signals were the same strength. Sometimes during the day I could
hear more man made noise on the vertical as expected, but not too much.

All in all, I expected more out of it, especially on DX. I am thinking
of building a bobtail array for this winter pointed towards Europe.

I am looking for advice on building a digital filter. I have a
real-time 16-bit audio stream, generated by sampling at 16kHz,
that I need to have high-pass filtered to eliminate PL tones.
The filtering is part of a custom repeater controller I'm running
on a Sun Sparcstation 10, so I have plenty of CPU available to run
the filter code. Years ago someone showed me a "recursive" digital
filter which was extremely simple, replacing each audio sample by
a weighting of the previous two samples (the weights determined the
filter cutoff). Unfortunately I don't remember the details. Can
anyone provide help, or at least some references to books or papers?

Source record: 109876

I bought a 50MHz AD7008 from Newark for $53...they have them in stock.

I went to Analog Device's office in Campbell to fetch a datasheet.
Whilst there, I let them know that they need to add a quadrature output
and make it just a little bit faster (60MHz). They said they have been
bombarded with data requests since the 73 artice!

I will be using one (with filtering) in a QRP rig for HF, driven by a
PIC micro. I use 50 pulse/rev. ALPS shaft encoders for my tuning device,
I don't like keypads. I get these from CIRKIT in England. Email me if
you want details.

Whilst we wait for quadrature outputs, does anyone have a good design
for a digitally bandswitched quadrature generator (one phase splitter
for each of the HF bands)?

>loop resistance and net current flow into the ground is vastly different
>between the two.

Tom,

The definition I had in mind is:
radiation resistance = total radiated power/(antenna current)^2

Acoording to a text book this is roughly:
7 Ohms for a 1/8 wl vertical over ground
30 Ohms " 1/4 " " " "
110 Ohms " 1/2 " " " "

Ground losses are supposed to be essentially inverse to these numbers,
so this is bad news for all the short multiband verticals
without ground plane.

That's the same definition I had in mind Moritz. I was trying to point
out the current is taken at the current maxima, not necessarily at the
feedpoint. The net feedpoint current (all the currents, not just the ones
from the transmission line) controls the I^2*R ground losses, not the
radiation resistance. Unless the feedpoint happens to have the current
maxima at the eart connection.

Any way, wrong newsgroup...so better off to the .antenna

: anyone provide help, or at least some references to books or papers?

My recommendation for digital filters which operate at a cutoff frequency which is a farily small fraction of the sample frequency is to build them as an analog of the continuous-time state variable filter. It's basically a cascade of two integrators, with feedback from each to a summing junction at the input. A simple sampled-time integrator is accomplished just by adding a constant, k, times the input to the current value. For a simple two-pole filter, appropriate weightings for the feedback terms would be -1.41 for the first integrator output and -1 for the second integrator output. Add those to the input sample. The high pass filtered output is the input plus the feedback, and that's also what's fed to the first integrator. The constant, k, is chosen to get the right cutoff frequency, and is something like 2*pi*fc/fs... Did I remember that right?

The reason for this configuration instead of the canonical sampled-time biquad is that when the cutoff frequency is a small fraction of the sampling frequency, you have a LOT of trouble with roundoff. Certain coefficients scale as basically the square of fc/fs. But in that state variable simulation, the coefficients scale linearly with fc/fs.

: >

Well, I would say that reference spurs of -6dBc are higher than
expected. If the loop filter was at fault, then shielding the
VCO would have no affect. As further evidence of VCO radiation,
when I had the top cover of the unit off and had a receiver tuned
to the VCO frequency, I could rattle metal tools together off the
bench up to two feet away and the VCO would produce microphonic
responses. And a spectrum analyzer with a "sniffer" probe would
pick up a strong signal in the general area.

I suspect that there's so much of this radiation being coupled into
the PLL circuitry that it's either modulating the divided VCO signal
going back to the PLL chip or somehow modulating the charge pump
output, perhaps driving the filter into nonlinearity. Whatever the
mechanism, it doesn't seem to be related to a bogus filter, and
I did fiddle around with that.

I'd be interested in hearing other possible explanations though.

Regards,
L

From: dgf@netcom.com
Message-ID: <dgfDH2o78.3xs@netcom.com>
Source record: 109888

I'd like to build a 5.0-5.5 MHz DDS or PLL synthesizer that I can use
as an external VFO for a conventional transceiver. I recall seeing an
article in QST or somewhere in the last couple of years on such a project.
Could someone tell me where to look, and if you'be built such a thing,
how well it works?

Thanks,

73 Dave WB0GAZ dgf@netcom.com

OK in the 1994 ARRL handbook the designs for the 1500W amp power supply show the need for a 234V AC line... What if I dont have a 234V plug in my house????

4929. ATV North Country Radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-26 00:00:00 UTC
From: timhynde@ix.netcom.com
Message-ID: <46o5s4$emm@ixnews3.ix.netcom.com>
Source record: 109890

I read a construction article last year for a 5 watt ATV tranciever
available as a kit from North Country Radio out of NY. The kit looked
very attractive and I thought the price of $179 for a 5 watt tranciever
was pretty fair. The article showed complete schem's & all but I would
be happier to get all the parts & PC board in 1 bag...

What concerns me is I have not seen them advertise in 73 or QST has
anyone built one of these or have any experience with this company?
Or any other suggestions for building ATV gear?

73,

Tim Hynde

Date: Sat, 28 Oct 1995 01:06:29 GMT

We've created a new email list devoted to homebrewing tube transmitters
and receivers (and associated equipment): Glowbugs. This list is a sort
of subset of the intersection of the Boatanchors and QRP lists.

To subscribe send an email to: listproc@theporch.com and only write:
subscribe glowbugs <your name>
and to unsub only write:
unsubscribe glowbugs

To send a message to the entire group use the address glowbugs@theporch.com

Topics include building with tubes, tube theory, xmtrs, rcvrs, power
supplies, antennas/leadins/tuners, skeds between members, homemade
components, parts suppliers, radio history, and anything else related
to the magic of Firebottles. Even for-sale/wanted-to-buy ads related
to tube gear are welcome.

For those of you into the "Heavy Metal" Boatanchor tube gear, then
don't forget the wonderful boatanchors@theporch.com mail list; to sub
send an email to listproc@theporch.com and only write:

From: phil@SANDH.COM
Message-ID: <000026500000060E@SANDH.COM>
Source record: 109901

I am interested in purchasing old mechanical calculators and slide rules.

I collect the old electro-mechanical "rotary" calculators that were made by Friden, Marchant, Monroe, and other manufacturers from the period of the 1900's through the late 1960's. I also collect non-electrical mechanical calculators. I am not interested in adding machines that print on tape or electronic calculators.

If you have an old mechanical calculator or slide rule collecting dust in a closet, please send me an e-mail message.

Hi Everyone,

I'm building a device like the Kansas City Tracker & Tuner and I am trying to figure out the computer interface for the Yeasu G-4500B AZ/EL Rotor. I've called Yeasu, but they don't have any written specs. I tech support person was nice enough to fax me the schematic of their GS232 box, which provides a RS-232 interface to the rotor.

What I need to know is the voltage range of the el & az positions indicators and how much current I need to drive the step up/down & left/right controls.

It should be a neat project. I'm using the Parallax Basic Stamp2 chip with two National Semiconductor ADC0831 A/D chips and a Maxim 233 TTL to RS-232 converter. This little device will receive the azimuth and elavation and doppler shift via an RS-232 port on my PC, and then it will position the antanna and tune the radio. I'm writing a little windows program which gets all this information from WinOrb using a DDE interface. If anyone is interested, let me know.

Thanks,
Kory

Source record: 109909

Gary's right - it's possible to build a pretty decent antenna for relatively few dollars. However, given the 200 kHz spacing between the desired and offending stations, Mr. Kwong may not be able to entirely eliminate the sideband of the offending station from spilling into his receiver passband. During my days in college, I had a similar reception situation to Mr. Kwong's. I never could get enough rejection from the rooftop antenna I rigged up during one semester to keep the distant FM signal free from the 'swish' of the adjacent station's sideband (local terrain was a factor), but it was good enough for background music to study by.

Hello out there. I built a small crystal radio, and I need some 2000 Ohm headphones for it. If anyone has a set lying around, or if you know where I could buy some, please let me know. Thanks in advance.

4950. TM-742A defect, HELP!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-29 00:00:00 UTC
From: daniel.lacasse@com18.com
Message-ID: <RERAAMHO.89B4@com18.com>
Source record: 109911

Hi all,

I own a TM-742A and have a problem with it now...

While I was searching which keys to press while powering onto change
the ON/OFF time, I tried (F + LOW) and POWER ON. The unit did not like it!

Now, my radio is like always ON. So I had to disconnet it from the
car battery.

If I reconnect it, it immediatly show me "- On -" then after two seconds
the brightness goes higher (pass from brightness level 6 (default) to
level 1 (my choice while it was working well). And then, after 2 more
seconds, all the display goes black. But the radio seems always to
be on because I can hear really low noise (like an open squelch)
from the external speaker.

I look up in the book if the key pressed were corresponding to a function
and it says 28 MHz selection of band (wide or narrow).

I tried to press MR key while reconnect to the battery for a reset but
if failed... :(

Is there something to do!?!

Daniel.Lacasse@com18.com

Christopher,

If no headsets turn up, you might try a crystal earphone. They're pretty high-impedance, and very efficient.

Tom, KA5NEE/9

4952. How to determine dBm when driving diode mixers with square waves

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-30 00:00:00 UTC
From: rohrwerk@netcom.com
Message-ID: <rohrwerkDH8x67.FC1@netcom.com>
Source record: 109913

It is said frequently that driving double balanced diode mixers with square waves is a good thing. Question is: how do you reckon the appropriate drive level in dBm with square waves? If a mixer is rated at, say, +7 dBm LO drive, does this mean +7 dBm as measured on a sine wave? If you drive it with a square wave, do you use about the same peak voltage as you would use with a +7 dBm square wave? Or do you calculate the average power of the square wave? Or what? :-)

In article <4718d0$1ie@ixnews5.ix.netcom.com> timhynde@ix.netcom.com (Tim Hynde ka8ddz/qrp Rochester, MI) writes:
>Hints & Kinks, November QST page 83
>
>Easy PL-259 connections?
>
>There is a description of how to solder a PL-259
>connector to coaxial cable. This suggestion was put
>forth by ARRL Technical advisor out of Texas, I'm not
>an engineer but this appears to me to be a poor design.
>
>
>a) it leaves the cable succeptable to water.
> (yes I know you wrap it, but wouldn't it be
> better to have the sheath inside the connector?
> I mean thats what the sheath is for isn't it?)

Doesn't much matter, it leaks anyway. You have to wrap it.
But at least he provides a solder bond all the way around
the back of the connector shell. This is better than just
depending on the slip fit of the plastic jacket.

>b) it appears to use the braid to support the cable
> (leaves the sheath with not much to do)

The braid is the strongest part of the cable. It should be
bearing the load. This is one good bit about this method.
But it's not that good a bit because a solder joint is a
poor substitute for a good mechanical connection.

>c) the author suggests to plug the holes with dabs of
> solder, weren't these designed for ground
> connections? Does not appear the braid comes up
> that far in this pictorial.

This has always been a weak point with PL connectors. Soldering
to the braid through the little holes doesn't make a very good
connection. That's one reason to consider the author's method.
By soldering all the way around the braid at the rear of the
connector, he forms a better electrical connection than just
trying to solder through the holes. OTOH he stands a much
better chance of melting the inner insulation because of the
amount of heat needed to make the joint a good one.

>d) the author suggests wrapping #14 wire around the braid
> which is still exposed. What does this accomplish?

This is just filler material so that the solder doesn't
have to bridge such a wide gap between the coax braid and
the shell of the connector. It's a good practice any time
you don't have a good mechanical fit to use filler material
before soldering. It's stronger than just letting the solder
bridge the gap. Uses less solder too.

>The intent is not to ridicule someone elses suggestion.
>Im just wondering why QST would publish this since it's
>in conflict with their own Handbook.

The method in the Handbook, though recomended by Amphenol,
isn't all that good either. If you must use a PL style
connector, and I try to avoid them when possible, then
you should use a Kings crimp connector. They offer a
mechanically strong and gas tight connection when applied
with the proper tooling (which costs over $200 BTW).
NASA approves them, and TV stations live by them, in
BNC and N too. (The tooling is bloody expensive, but
it'll last a lifetime in amateur use. The connectors
themselves are pretty inexpensive, no more than solder
on connectors.)

Soldered connections just aren't as reliable as a gas tight
crimp connection *properly applied*. Don't be put off of
crimp connectors by cheap RS junk connectors crimped with
a cheap pair of pliers. A proper crimp connector, designed
for the cable you're using it on, and installed with the
proper tooling for the cable and connector you are using,
is the best connection you can hope to make. And there's
zero chance of melting the inner insulation and ruining
the connection.

I've convinced several doubters by swinging from a piece
of RG-8 screwed to a support panel by one of these connectors.
The connector never fails, but the RG-8 gets noticably thinner,
I'm a big guy.

From: sabinw@crpl.cedar-rapids.lib.ia.us
Message-ID: <472iah$pl0@flood.weeg.uiowa.edu>
Source record: 109917

John Seboldt asks about square wave diode mixer drive as compared to sine wave. My custom has been to use a square wave of *current* with the same peak amplitude as the peak amplitude of a sine wave. The drive power will be 2 or 3 dB greater, but in practice mixers are quite tolerant of a little additional power. When the square wave of *current* can actually be achieved (at very high frequencies it is very difficult) the mixer intermodulation performance can be significantly improved, if all other conditions such as resistive IF load can be met. The diodes tend to "square off" the voltage waveform, so it is the current waveform that is most important. The best driver circuit is a current source rather than a voltage source. Bill Sabin W0IYH.

I have had no luck at all in locating the following articles that
were cited by a fellow from Australia about a month ago:

Joseph Carr, "Small Loop Antennas for MW, AM BCB, LF and VLF Reception"
Elektor Electronics, June 1994 and July 1994

J. Barendrecht, "Wideband Active Loop Antenna"
Elecktor Electronics, March '95

Elecktor Electronics is a Dutch magazine that is available in English. There
is an address in New Hampshire, but I haven't been able to get a response
yet. If anyone out there has access to these two articles, I would be very
happy :) to have copies.

Thanks in advance for your assistance.

Regards,

Chris Trask

Yes, we have tried matching transformers as well. First they have about three db insertion loss. Secondly, the higher impedance has so much more audio recovery that they are worth the additional expense. Most stereo phones are 40 ohm impedance and even those units are not as sensitive as the crystal "ear plug" units.

I am looking for information to build a receiver for a Radio Control
Aircraft. I am currently using a 5 channel Futaba FM PWM (72MHz) system
and I thought it would be a fun project to build a little receiver.
I have never used the 6m band for RC control and am wondering if any-one
could give me information about modifying my Futaba radio, building new
radios, etc.
One of the problems that motivated me to look into a homebrew solution is
that I have an interest in flying wings and they require servo mixers. I
think I understand the theory to build one but I am not positive. If anyone
knows of a design for servo mixers I would be greatful for any hints.

Source record: 109924

The local oscillator port of a double balanced mixer sees the equivalent of 2 diodes in series. Once the diodes turn on, the LO voltage is clamped at the diodes' forward voltage. Assuming that the diodes clamp to about .7 volts each, and there are 2 series diodes in the LO voltage path, you get an LO voltage requirement of about 1.5 Vpp, or 0.5 Vrms for a sine wave. Using the familiar rule P=(E^2)/R, this equates to 5 milliwatts (7 dBm)for in a 50 ohm system. If you use a square wave, just be sure that you drive the same 1.5 Vpp signal into the DBM LO port and you'll be fine.

Larry, what you are really talking about is the old fashioned AC
capacitor used in motor starting. First I would suggestion you simply
ask for a motor starting capacitor used in antenna rotors. They are just
about the right value you need.
If you would like to make your own, place diodes in series with any
polaraized capacitor in the right direction to prevent reverse polarity
and do a similar thing with another capacitor/diode in the reverse
direction. Wire them in parallel. This is a very suitable replacement often
better than the original and far cheaper but larger in volume. 73 Cliff W6HDO

4967. Land Mobile Radio FAQ needs your input!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-10-31 00:00:00 UTC
From: randolph@est.enet.dec.com
Message-ID: <4760ev$ibj@mrnews.mro.dec.com>
Source record: 109928
Cross-posted to: rec.radio.swap,rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

[I'm including part of the Motorola listings from the FAQ at the bottom, so you all can get a look at how it's presented, and what info I need. I need to do a lot of cleaning up and organizing of this somewhat scattered listing format!]

The Land Mobile Radio FAQ is now under way... I need your support!

What is it?

A listing of those surplus police and taxicab radios from the various manufacturers, how to identify them, what band they're on, how easy it is to tweak them into the ham bands, average price used, etc., all in one file for your flea market shopping convenience!

What it's not is a mod manual. You won't find out HOW to do the mods in the FAQ. That's up to you. You will find out where to get the manufacturer's manuals, most of which have detailed tuning procedures. Some of the radios can only be programmed by the manufacturer, and/or by using the manufacturer's proprietary software. Such details will be in the FAQ.

I'd like to include any and all mobile or handheld radios aimed at the commercial or public service market. Many of these out-perform the imported synthesized units by a long shot, are cheaper, and make great ham rigs! Let's put these great radios back to work and on the air!

I NEED YOUR INPUT TO MAKE THIS A REALITY!

You don't need to mail me manuals or anything like that, unless you WANT to. All I ask is a few bits of data for any of these radios you or your friends may have worked on in the past. If you've put one on the air, you've had to answer these questions, so fill 'em out and send 'em in!

Model? Manufacturer, model name (like Mastr II, Syntor, Delta, etc.), model number

Band? These radios are usually made for use in a specific band of frequencies, like 30-50 MHz, 150-170 MHz, 450-470 MHz, etc.

Freq control? Crystal, synthesized/ROM programmed, synthesized/microprocessor programmed

Average price? What did you pay? What prices did you see when shopping? New or used?

Manual price? How much did the manual cost?

Mod difficulty? How hard was it to get it tuned to ham band?
Easy: re-crystal, tweak a few tuning screws
Difficult: program a new ROM, swap a few parts
Extremely difficult: Major modification and re-design
of some circuits, you must pay
authorized technician to use
manufacturer's software

How to indentify? What details do you need to know to tell these radios
apart? Does the serial number tell you anything? Does
the Model number? Are there physical differences?
This is the stuff you need to know when sorting
through the radios at the flea markets. This
information is usually in the manufacturer's manuals
in great detail.

I will re-post this notice about every other week for a while, until the FAQ
is somewhat filled out.

My net address is: randolph@est.enet.dec.com
All information, network pointers, periodical references, anything, is
appreciated, and thanks in advance!

-Tom R. N1OOQ randolph@est.enet.dec.com

amencke@panix.com (Andres Mencke) wrote:

>Is there a technique called "Coherent CW" for
>low power, DX communications?

Yes, BUT both stations must be so equiped, or at least must be using keyboards.

The technique is to sychronize sending with master reference (WWV fer example).The reciever then samples each "time slot" (time slot would be "dit" length, or 1/2 1/3)and makes a yes/no decision about if the signal was present. If yes, then it fills the whole time slot with a tone. If no, it fills the slot with silence.

It is also possible to lock the reference clock to the incoming signal, by looking for transitions. This is required to some degree even if syncing to WWV, due to variable prop delays..

The keyers used would not "start" untill the beginning of the next time slot, so took a little getting used to. Also the reciever contributes one time slot of delay.

>Where can I find more information about it?

ARRL handbook had section on it for at least a couple of years..maybe 84 to '86...

You can probably do nearly as well using DSP techniques, CCW is in fact a DSP technique. CCW filters use knowlege of where the edges SHOULD be in order to reduce noise.

I don't see why most of the handbook block diagram couldn't be implimented in a DSP.

Happy building.

Hello Allen
The following Smith Chart program references might be of
use. I believe they are Shareware initially:

SCAT : Smith Charting "S" Parameters particularly HF Amplifiers

by Aciran Software (In Scotland I believe)

SMITTY - Transmission line calcs. by K1TD

The RFC Program .... A very nice Smith Chart program

by Giorgio Fontana (I downloaded mine some time ago from the
One Stop LLBBS in the states)

PUFF - Electrical CAD by California Institute of Technology

Techplot Test Drive by Polysoft
Smith / Gaussian / complex etc

One of the "Heavyweights" is MathCad so long as you have the
Electronic Book part to the program. That has some nice Smith
Charting possibilities.

>Which immediately begs the question, "What of mixers rated for +17dBm or even
>+27dBm LO input?" After all, +27dBm is 1/2 watt, and at 50 ohms, this is 5

These guys have extra diodes in each leg, so the voltage requirement is higher.
Some also have an RC network in each leg. See the Merrimac RF and Microwave
Processing catalog (I have a 1992 edition) Table I, p. 1.3..

BTW, I think that if you use a square-wave, the peak drive voltage can be lower
for equal efficiency. A sinewave drive should be high-enough level so that it
is significantly clipped by the mixer (thus becoming a square wave). Think of it
as a valve which turns on when the drive exceeds the threshold. If the valve
only turns on for a small fraction of a cycle, you won't get much water (signal)
through it).

Most auto parts houses sell analog tachs.
Buy two. Seems like you just need relative revs.

Even if you don't have 4 cyl engines you will still get output to the
tachs
from the ignition systems.

Message-ID: <9510311820387626@minfox.com>
Source record: 109938

N> So if any one out there knows what the IF10D is made up of , i
>would be greatful if you could give me a few pointers.

Greetings ROB:

You got my curiosity up as I own a TS-50S which I use as a
mobile and did not realize that it had a computer interface jack. As
I only use mine mobile I have not had the occasion to look into
interfacing it (until now).

I have written a transceiver control program for my TS-850S
which displays the IF spectrum in colour graphics and allows one to
point at a signal with the mouse and leap tune the transceiver to it
with the click of a mouse button.

I to was not willing to pay the price for an RS-232C to TTL
level converter box either and I ended up building one with a quad op
amp and a 5 volt zener diode with limiting resistor. I power it from the
computer port and use a 7660 power inverter to generate the negative
polarity voltage needed for the RS-232C interface. At the time I was not
aware of the Maxim Semiconductor MAX232.

The MAX232 is a chip designed to do TTL-RS232C level conversion
with one chip. It has a built in negative voltage charge pump. All you
need is this chip and an external charge pump capacitor to complete the
level conversions. It costs about $3.00 in single unit quantities and
should be commonly available. There is a version of the chip with the
capacitor built in that cost a little more. Check out Maxim's
application information for connection details.

I took a look at my TS-50S schematic and noticed that 5 volt
power is available on the CN6 DIN connector which I believe could be
used to power the MAX232. The TXD, RXD, CTS and RTS serial com port
signals are passed through individual RF low pass filters (series 470
Ohm resistor with shunt 0.01uF capacitor) directly to the micro
controller port pins. PLEASE NOTE that the application of excessive or
wrong polarity voltage on one of these pins could possibly destroy the
microprocessor!!! This appears to be a typical 0 Volts logical low and 5
Volts logical high CMOS interface but you may wish to play it safe
by limiting the logical highs to +4V as the micro controller is powered
one diode junction voltage drop below 5V (to provide for battery backup
switching).

I hope this information is of some help. Hopefully someone will
respond with the exact details of the Kenwood IF-10 schematic which you
could probably duplicate at a low cost.

If you get any other information on the TS-50S I would
appreciate it if you would pass it on to me.

Good luck with your project.

Yes, I have one. It did cost nearly much as a second hand HP141 setup,
but at least you can lift it.
Basically - It works very well, but the lack of any sort of output means
that you can't record readings.

Even in the UK it took months to get one delivered.

Crimping deleted
}
}Gary
}--
I have to agree with the original post. The method described by the author
of the article is poor overall. A properly done PL259 does make good
contact and will work much better than the method described in that article.

One of the "secrets" to making a good braid connection is to pre-tin the
PL259 shell. It will still be warm when assembled which will aid the follow up
soldering. It is also necessary to run your soldering iron all the way around the shell
to heat up the different areas of the braid/shell interface causing the solder to wick
inside.

The other thing to do is use QUALITY COAX! Poor coax won't have enough braid to make
a good solder connection to in the first place! The hardest of the coaxes to solder is the
foam
stuff, even though it has better loss characteristics than standard rg8 or rg213.
The air when heated in the foam wants to expand and push the foam out the holes.
I'll admit to always having problems there. The only foam coax I have been sucessiful
at is Belden 9914, which has foil around it!

The poor ol' PL259 is a bad enough rf connector to begin with. Improper
assembly doesn't help and the method described in that article is just that!

73,

Bruce, WB4YUC

}NASA approves them, and TV stations live by them, in
}BNC and N too. (The tooling is bloody expensive, but
}it'll last a lifetime in amateur use. The connectors
}themselves are pretty inexpensive, no more than solder
}on connectors.)
Gary,
There's no such thing as a gas tight crimp on braid. There will always be
air, or gas in between the individual wires. A secondary sealing method
must be used in order to get this effect.

You're right about assembly, it must
be done properly. More often than not, when purchasing commercially
manufactured cables, they are improperly done. The properly manufactured cables
are quite expensive by comparision and the average ham probably won't want
to spend the difference, especially if he can't immediately tell the difference
between the two.

This sounds like the method developed for using off size Radio Shack coax
for CB by a new age technical guru named Bill Shoop. Bill Stripped the
jacket, Heated the shield, Invoked the connection, and Taped it up.

This connection method has become the standard at CB shops across the
nation. CB shops often refer to this method by an abbreviated name, it's a
"BS-CB-S-H-I-T" type connection. I'm happy to see it's finally appeared in
an Amateur publication, although I expected 73 would be the first to
publish it.

Personally, I've always found the methods shown in old handbooks work
quite well.

>the average power of the square wave? Or what? :-)

With almost all parts, you are worried about either
exceeding a voltage or power limit. With mixers like
the SBL-1, you are worried about the power limit.

Thus, I'd calculate the power absorbed by the mixer
when figuring out the maximum driving level. This normally
results in the best IMD performance, at least before the
diodes are destroyed.

OTTH, for the mixer to work you do in fact have to turn
on the diodes by exceeding the "threshold voltage." Thus,
you want to figure out the voltage if you are investigating
this extreme.

+ 7 dBm is usually a nice happy medium between the two
extremes, so most people don't bother with a detailed
analysis.

Aha. Thanks for this info, Carl. You don't get this impression from the
MiniCircuits catalog, which shows schematically single diodes. But you can
infer it from the SWR curves, which maintain a reasonably low SWR for rated
LO input power over the range of mixers from +7dBm to +27dBm. So the
higher-level mixers use additional diodes to handle higher voltage _and_
higher current. These allow a higher RF input compression point.

>mixers from +7dBm to +27dBm. So the higher-level mixers use
>additional diodes to handle high higher voltage _and_ higher current.
>These allow a higher RF input compression point.

The original question that was raised was whether a square wave drive
would improve the IMD of a DBM. The response was that if a square wave
of current were used rather than a square wave of voltage the diodes
would behave more like an ideal switch, the idea being that the
on-resistance would be low over the entire half cycle and less
time-varying. My work with mixers has verified this many times.
But at very high frequencies this square wave of current is tough
to get. Bill Sabin W0IYH

>etc.

An inadequate Earth terminal can cause some problems, but poor station layout is a much more severe problem. It's possible, and often done, to "float" the station independent of Earth, and still provide adequate strike surge protection. This is routinely done for broadcast facilities located on top of tall buildings for example. In principle (and in practice) you don't care what the absolute potential is of your system reference. It can float to any arbitrary value during a surge or strike, *as long as everything in the station follows that reference potential*. This is the key facilities layout issue. *There must only be one system reference point*, and *everything* has to tie or clamp to it by a low impedance path.

>Don't operate your station during a severe lightning storm. Disconnect
>all your radio equipment including other equipment in the vicinity of
>your radio equipment. By disconnect, I mean UNPLUG power cables from
>the mains, and UNPLUG antenna cables. You can go further and ground
>the termination of the antenna cable.

Note, a lightning bolt, which has travelled miles through open air, will not be deterred by a few inches of air between your equipment and the antenna cable, *unless you offer it a lower impedance path to take*. In facilities layout, establishing low impedance paths from the strike conductors to Earth can offer that low impedance path. But that's sometimes difficult to do, so the alternative is to let all the equipment *float with the surge*. That requires maintaining a controlled copper connection between all the equipment and the

surge conductor. Small air gaps (and small in this context is anything
less than the distance to a good Earth terminal) can increase hazards.

Alternatively, you can try, as you suggest, to *totally* isolate
the equipment from *any* path the surge may wish to travel. That
requires disconnecting, and separating well away from the equipment,
all conductors. Still, aircraft in flight, as well isolated from
other conductors as you can get, do sometimes take damaging strikes
from uncontrolled currents using the conductive aircraft as a bridging
conductor in the air path. It is much preferred to offer the surge
a *controlled* path over which to travel rather than to let it determine
which path it wishes to take in a (seemingly) random manner.

>Even a good ground system will not protect you from a direct strike,
>cause all you need is a little trickle past the system to do the
>damage.

A good Earth connection can aid in directing surge. It will not
prevent surge, and if facilities layout is done incorrectly, it
can allow surge to do *more* damage.

>I'm not kidding...

Neither am I. Protecting from surge is simple in principle, but the
details of the implementation *count for nearly everything*. Simple
(minded) approaches can *make the problem worse*. And poor execution
of even good approaches can be catastrophic. This is one area where
a little knowledge can be a dangerous thing. Every amateur should
understand this topic *in complete detail* so that they can take
protective steps which won't inadvertently *make the risks greater*.

>difference, as you are trying to make out.

Indeed I have read textbooks. There are at least three separate issues here which you are co-mingling. Lets establish some givens first.

For the types of antennas we are discussing, it is primarily the current, and the current distribution, in the element which determines its radiation resistance.

For a finite driving voltage, a resonant antenna will have more current distributed along its length than a non-resonant antenna.

This can be simply seen from Ohm's Law for impedances. Every antenna has a resistance, R, of some finite value, and some reactance, X, which can be a finite value or zero. The antenna current, I, for a constant driving voltage, E, is

I = E / sqrt(R^2 + X^2)

For any E and R, I tends to maximum when X tends to zero. So there is a difference whether the antenna is resonant or not.

Now for resonance, we need a certain electrical length, and that length needs to be a half-wave, or some multiple thereof, to give us the proper *current standing wave* for maximum radiation, IE for an ideal current distribution on the linear antenna circuit, we need a current standing wave.

We can get that electrical length several ways. One way, generally the most efficient way, is for the antenna's physical length to be the same as its electrical length. We call such elements "naturally" resonant.

A half-wave element is naturally resonant.

Another way is to use a lumped network to "tune out" the reactance and make the antenna's electrical length a resonant one. The problem with this approach is that the lumped network does not contribute to the antenna's radiation, but it does contribute to the antenna *system* losses. So lumped reactance "loaded" antennas are typically less efficient radiators than "naturally" resonant antennas.

Yet another way of making an antenna naturally resonant and to support the standing wave is to use a *counterpoise*. This is what we do with a quarter-wave element. We give it another quarter-wave below the feedpoint so that its total length is a naturally resonant half-wave. That quarter-wave can be an actual element, or it can be a conductive sheet acting as a *current mirror*. The conductance of that sheet *directly* affects antenna radiation efficiency because it is *part of the antenna*.

Thus for antennas over "ground", "ground" is not part of a half-wave antenna, but "ground" makes up *half* of a quarterwave antenna. This is a *fundamental* difference between the two antenna types.

The location of the feedpoint is irrelevant to the radiation efficiency of an antenna. (Though the location of the feedpoint can affect the efficiency of the antenna *feed system* in several practical ways.) In principle, the feedpoint can be located anywhere along the length of any antenna. Typically, we prefer to locate the feedpoint in the center of the effective electrical half-wave because that offers us best practical *feed system* efficiency (a separate thing from *antenna* radiation efficiency) due to electrical *balance*. However, for practical mechnaical reasons, we may locate the feedpoint elsewhere. This often complicates the feed system electrically, and may in many cases be less efficient.

All right, so it should be clear that there is a fundamental difference between "ground" independent antennas and antennas that use "ground" as a counterpoise or "current mirror". The latter need "ground" to work, the former do not.

None of this has yet addressed *parasitic* near field losses. That's
a separate issue. Any antenna near a lossy conductor (such as Earth)
will induce a field in that conductor. The loss resistance of that
lossy parasitic conductor will then convert some of the field energy
to heat. This *directly* reduces the antenna *system* efficiency.
It doesn't directly reduce *antenna* efficiency, however, unless that
lossy conductor is *part of the antenna* as with a quarter-wave using
Earth as its current mirror. So, if the antenna is ground independent,
the antenna *system* efficiency will be greater if the antenna is located
in *free space*, far from lossy parasitic conductors.

>Think of a walkie talkie: no half wave, no quarter wave or counterweight,
>but it works.

HT antennas are either electrical quarter-waves, fed with the HT body,
and the human body holding it, acting as the current mirror counterpoise,
IE acting as "ground", or they are electrical half-wave antennas fed with
a matching transformer and operating with *ground independence*. The latter
are obviously more efficient radiators since they don't require the lossy
human body to be *part of the antenna*.

Those -1565s are nice, even as a source of parts. That's where mine went. The power supply is beefier than the supply in certain commercial "kilowatt" amps. Collins....

Did you get the case? A regular boat-anchor. I know where there's a -1565 case and faceplate in a local lake, at about 50 feet.

There's a manual tuning method on these that should have you on the top of 220 instantly...if not, padding the cavity is relatively easy. You'll have to do a little more surgery to get it to 432.

I haven't ever seen any info on a conversion of one of these amps, probably because they're relatively scarce and because they weigh 250+ lbs. with the case and front cover. My SK elmer WD5GJA used to describe these as having a built-in hernia.

Well, there was a lot written about it in the early eighties.
However, it fell by the wayside, partly because special
equipment was needed (every oscillator in your TX / RX should be
very accurate). However, today with DSP adn DDS it might another
matter.

I have read however about another problem with CCW: The performance
was reported to fall considerably short of the high theoretical ex-
pectations. Anyone knows more?

There's a section in the older ARRL handbooks. It's a method of using very narrow filters. If you look at their system, it's really one channel of a Fourier Transform operating at 1 kHz, with a one tenth second sample interval using analog hardware instead of a computer. (Actually, since it's using real valued analog representations for the data, it's more like a Hartley Transform). The Coherent part comes from synchronizing the sample interval with the transmission's bit timing. And the frequency locking comes from the stability requirement from using the 20some Hz wide channel of the filter.

An add on audio DSP unit or FFT computer program that ran a spectral analysis with the same sample period would give similar results, especially if it ran overlapped samples or was able to synch. the sample period to the bit timing. You'd still need a very stable receiver and transmitter.

Seems like a neat application. Would be great if you could submitt a
short description to the L.O.S.A when finished.

List Of Stamp Applications (L.O.S.A for short)
==

If you have done something with the BASIC Stamp (big or small)
that you are willing to tell others please use the form below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Then e-mail the form to:

cj@algonet.se

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill in
the L.O.S.A form on the Web-page...

http://www.algonet.se/~cj/losa.html

When there are a bunch of contributions I'm going to post the L.O.S.A
to this list, upload it to Parallax, Inc. FTP-site and send it to the
following Usenet groups. I will update it approx. once a month.

5005. AM-1565/URC Power Amplifier

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-02 00:00:00 UTC
From: hbrown@ew0203.resd
Message-ID: <47av8a$jq6@morgan.vf.mmc.com>
Source record: 109959

I found an AM-1565/URC Power Amp at a local hamfest. Does anyone have any info on it such as a schematic, wiring info, etc.?

The person selling it had a copy of an add from Fair Radio saying that is part of SRC-20 225 to 399.5 MHz, 100 watt radio set. It has 2 each 4CX250K's in a cavity and a couple or relays that look like they are used for bypassing the amplifier.

There is a lot of gearing involved that tunes the output and I assume the input cavity. There is a rough frequency dial in 10 MHz increments that if it is close, looks like 222 and 432 could be reached. It is extremely well made and I would like to put it on one of the bands.

Help or suggestions on where I can find help would be appreciated.

73, Harry, W3IIT

From: mack@mails.imed.COM
Message-ID: <9510028153.AA815338817@mails.imed.com>
Source record: 109960

From: tomb@lsid.hp.com (Tom Bruhns):
>Which immediately begs the question, "What of mixers rated for +17dBm or even
>+27dBm LO input?"

I don't have any of my Mini-Circuits books here at work to be 100% sure, but I believe that the +17dbm mixers use two diodes in series in each leg vs one in each leg for the +7dbm mixers. Asimilar situation exists for the +27dbm mixers.

> strike surge protection....

Yes, you can, but you can easily make a mistake and kill yourself or destroy all your equipment if you don't design and implement everything perfectly and operate in a thunderstorm. You can also protect your ham equipment from lightning and conduct the lightning from the ham shack back into every other electrical device in the house through the power lines. It's also easy for a "rogue ground" to sneak in and screw up the whole setup. (e.g. phone lines, computer cables, cleaning ladies with vacuum cleaners plugged in outside your "safe zone", etc.)

I'm not saying "floating" systems are bad, just that they aren't always easy, obvious, or practical to implement. You can also still get damage with a floating system, because of residual resistances and AC affects. They can be good, but they aren't perfect. I would still stay away during lightning storms if I could.

5008. How does a "circulator" work?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-02 00:00:00 UTC
From: Douglas Braun <douglasbraun@hol.gr>
Message-ID: <47a3ee$mah@newsflash.hol.gr>
Source record: 109962
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics

There is a nifty RF device called a "circulator". It has three terminals.
RF energy fed into terminal A comes out terminal B, energy fed into terminal
B comes out terminal C, and energy fed into terminal C comes out terminal A.

I have seen descriptions of these for microwaves, where they are built from
waveguide and ferrite. But I would like to make one for 28 MHz out of discrete
components. Has anyone ever seen a description of how these really work,
or a circuit for one? Is it even possible to make one from discrete
components (coils, transformers, etc.), or does the operation depend on
some magical property of ferrite?

I am trying to connect a transverter to a HF radio (TS-50) without a
seperate transverter connection, and one of these could elegantly solve
the T/R switching problem...

Thanks,

Doug Braun (SV/N1OWU)

This is more in response to the other responses to this thread.
It is attached here for continuity.

The mixing process can be performed by devices that are either nonlinear
or devices that are time-variant. Many people assume that because diodes
are used, it is their nonlinear behavior that is the desired parameter.

In fact, the ideal situation is for the diodes to be acting as time-
variant, ideal switches. The best way to assure this behavior is to
get the diodes turned on or turned off as rapidly as possible. What better
way than to use an ideal square wave? Within limits, increasing the lo
amplitude has a similar effect, ie the rate-of-change around zero crossing
is increased.

Because the rf signal is effectively in series with the lo drive if it
becomes large enough, it can decrease the diode current during part of the
rf cycle. This can drop the operating point back into the undesired "nonlinear"
part of the curve. The way this is partially overcome is to add additional
diodes and/or RC networks to the mixer and increase the lo power level. The
higher rf signals are dispersed across more diodes and when the RC networks
are used, they help keep the rf signal from dominating during lo zero crossings.

For further info on this subject, one of the better referances I have seen
is Watkins-Johnson "Tech-notes" Vol 8. No 2 - March/April 1981 and No 3 -
May/June 1981. This info is also reproduced in any W-J catalog.
BTW the catalog is a wealth of tech info on this as well as other topics
such as power dividers, broad-band amps, etc.

I do not work for W-J, I work for Mrs. Stewart :-)

The best way to think of the hard switched diode is just as a device
working in a *very* non-linear region of its response curve. You can't
get much more non-linear than a snap transition from on to off.

I think it was more a matter of, if you're going to go to the
trouble to use a coherent signal, you might as well use a better
encoding as well. At the time that coherent operation became
practical for amateurs to implement, better coders and decoders
also became available. It turned out that the benefit of going
to a better encoding was more cost effective than the benefit
of using coherent signals, so the latter method isn't widely
used. The two used together, however, provide impressive results
under the right conditions. The problem is, we rarely work with
signals that weak, so there's little need to go the last mile.

Petit touted coherent CW for the QRPp operator, but they generally
prefer very simple equipment. And he touted it for EME, but
Rayleigh scattering broadens the signal return, IE Doppler shifts
it, negating some of the advanatage of the very narrow effective
bandwidth of coherent CW transmission systems.

I have a problem with this concept of "electrical mass" needed for
the signal to "push against". To me that smacks of the same sort
of reasoning which says a rocket can't work in vacuum because the
exhaust has nothing to *push against*. That's false, of course,
and I think the electrical mass model is at best misleading as an
analogy, and false as a physical fact.

The reason the quarterwave needs a counterpoise is to *support the
standing wave*. For a standing wave to be self-supporting, it must
have a natural current (or voltage) zero at each end, IE be dipolar.
A half-wave element does have a standing wave current zero at each end,
but a quarter-wave element does not, it's zero at one end and max at
the other. The counterpoise electrically extends the quarter-wave to
the current zero so that the standing wave becomes self-supporting.

Wes Stewart (N7WS@azstarnet.com) wrote:

: Try it this way...

: Connect the polarized caps in series, negative to negative.
: Shunt each cap with a diode; cathode to positive, anode to
: capacitor center-tap.

That looks like it should work. Please note, however, that for small voltage swings (less than 0.7 volts) the effective capacitance is half of what it is for larger swings. In most applications this will not make a heck of a lot of difference, but it is something to be aware of.

The use of schottkey (sp?) diodes should reduce the threshold of this effect to around 0.2 to 0.3 volts.

To: Anyone who received my specification list on the WSR-1 Weather Satellite Receiver System.

From: Mark Wyman (WOWEE@MSN.COM)

If you received my specification sheet before 11-1-95, the second IF specification under the ceramic filter should read +-15 Khz wide, not 15 kHz wide. This specification makes a large difference in the performance of the radio. If it were only 15 Khz wide, the Dopplar shift of the moving satellite would move the frequency outside of the receivable band. 30 Khz is much better, but notice also that the useable bandwidth is closer to 50 KHz due to the "skirts" of the crytal filter not being very steep. I hope this error did'nt turn too many of you away from purchaseing this system.

Again sorry for the error;
Mark Wyman

Just as the vector sum of momentum of the rocket's exhaust and the momentum of the rocket must be zero, the sum of charge passing a point must be zero. If you push charge into, and pull charge out of, the end of an antenna, be it half-wave or other, there must be a corresponding current on the _other_ side--the feedline side--of that point which represents the end of the antenna.

I don't have a problem with the idea that that current ends up charging capacitance between/among various conductive objects like feedlines and antenna elements and radials and whatever else is or is not around, but the vector sum of currents into any chosen (effectively infinitely small) node must be zero.

(If the node you are dealing with is small, but not infinitely small, then you can store charge within the node and end up with currents into it that don't sum quite to zero. That will happen if you consider a short section of the antenna wire: the current at one end will be different than the current at the other end, in general.)

I don't have any argument with what you're saying at all, but I don't
see how it addresses the point. After all, we are dealing with an AC signal,
and what flows one way during one half of the cycle flows the other during
the other half, so net charge movement is zero. Some *energy* is lost in the
process, however, both copper loss, and if the structure is long enough with
respect to the alternating charge motions, radiation loss. But the charge
all stays in the antenna, in the standing wave. It doesn't go gallivanting
off across the countryside, it just bounces back and forth from one current
zero to the other, reversing direction as the potential poles at each
end of the antenna reflect it back toward the other end.

The charge in an antenna is like a kid on a swing, you give it a little
pat on the butt and off it goes, then back it comes at the natural
resonant frequency of the swing. If you don't give it another pat,
the amplitude of the swings will decline over time due to losses,
(swing friction losses at the pivot, analogous to copper losses in
an antenna, and wind resistance losses of the child's motion, analogous

to radiation loss) but if you give it another little pat at exactly
the right time, and of exactly the right energy, it'll go on swinging
at the same amplitude again and again, losing energy on every swing,
but gaining it back with every pat.

There's no net charge flow in a naturally resonant antenna, charge just
rebounds back and forth in the standing wave, getting its timed little
"pat" from the alternating potential at the feedpoint. There is a net energy
flow, however, into the antenna from the driving source, and out of the
antenna as radiation and heat. It's not a closed circuit, it's an open
system.

I don't see how this relates to the need for an external "electrical
mass" (is that measured in kilograms?) or the idea that you need it
to "push against" however.

Gary

<SNIP!>

Coming in late to this thread - have you considered a 1 chip solution?
Specifically one of the Philips series of PLL Frequency Synthesizer
chips for use in AM/FM radios. RF inputs of 512Khz-30Mhz or
30Mhz-150Mhz.

SAA 1075, TSA 6057, TSA 6060 or for <30Mhz, TDA 8735

For myself, I'd like to be able to source small quantities of ONE of
the above!
Or find a similar product from any other manufacturer.

Cheers, Murray

Well, when a good switch is *on*, its IV curve is a straight line.
When it's *off*, its IV curve is also a straight line. Sounds linear
to me :-) I'm glad too. Imagine the rf noise from all the light
switches in the house if it were otherwise.

>>>A halfwave antenna *does not require ground* to function.

Hi Gary,

Thank you for you posting. Pleas note however, that in the paragraph I
cite below, you repeat what I have been trying to say in the
course of this thread.

The above statements are at least misleading, as they suggest
that ground losses, which are a problem with a 1/4 wave vertical
unless you provide a proper radial system do not exist
for a 1/2 wave vertical.

:Any antenna near a lossy conductor (such as Earth)
:will induce a field in that conductor. The loss resistance of that
:lossy parasitic conductor will then convert some of the field energy
:to heat. This *directly* reduces the antenna *system* efficiency.

Hello all!

I'm still looking for schematics for a very simple, single freqency
crystal controlled 8m cw transmitter and/or receiver. I have found
lots of fancy, tunable units, etc...what I need is a very stable,
one frequency unit. It's for telemetry - low power is fine!

Email to ejacksch@bnr.ca would be greatly appreciated.

Thanks,
Eric.

A DBM should be thought of as a signal multiplier, not as a non-linear processor. True, a non-linear processor accomplishees signal multiplication because its transfer function can be described by exponentials (remember from high school math that adding exponentials is the same as multiplying the arguments?).
The DBM actually multiplies the RF signal by +1 or -1 according to which half-cycle of the LO is driving the mixer. It's just a fancy diode switch which reverses the signal phase according to LO input. Multiplying AC signals produces terms which include the sum and difference of the inputs...mixing, as we call it.

Doug,
There is a device called lumped elements circulator, it seems to
be made from three windings on a magnetically biased core or so.
They have been used in 2 meter repeaters with a single antenna.
But surely this is nothing that can be made easier than a T/R
switch and attenuator you are looking for. And they are prone to
saturation and other effects.

In the commercial applications I've seen, the arrangement is just to connect the capacitors back to back in series without any other network on the center point. These were used in applications involving a slowly varying DC bias of unknown polarity, with a small AC signal being coupled through. In this case, there is apparently plenty of time for the reverse-biased capacitor to leak and transfer charge to the other one. There shouldn't be any harm in protecting the capacitors with diodes, a leaky capacitor is probably about as non-linear as a conducting diode anyway, though neither condition should occur in normal operation. This is because the AC signal is low enough in level and high enough in frequency that the capacitors aren't charged and discharged more than a few mV by the AC. Thus changes in the effective capacitance don't affect the level of signal being coupled through. Applications that don't meet the low-ripple criteria (audio filters, speaker crossovers, etc) use a genuine bi-polarized capacitor, which really isn't much more expensive than the two capacitors it replaces, especially in the smaller values.

>
>The use of schottkey (sp?) diodes should reduce the threshold of this
>effect to around 0.2 to 0.3 volts.

Probably a bad idea unless the capacitors are likely to be damaged by the 0.7 V from a regular diode. Since the diodes will conduct sooner, distortion might increase. Schottky diodes are also rather leaky when reverse-biased. The inverse-series capacitor crutch should be used only if the ripple voltage is small. In this case, the effective capacitance will be fairly linear and 1/2 the capacitance of each capacitor. The effective capacitance will increase some during transient conditions but the impedance of the capacitor array is already very low compared to the rest of the circuit so it doesn't make much difference.

>depend on some magical property of ferrite?

Isolators, circulators and their ilk do depend on a "magical" property
of the ferrite. The ferrite is within a strong magnetic field, which
causes the little iron atoms to precess (in a preferred direction).
This makes one circular polarization of EM energy travel faster through
the medium than the other, and since linear polarization can be seen as
the sum of two opposite circular polarizations, the polarization
direction of a linearly polarized EM wave will rotate. This is Faraday
rotation (which the EME and satellite people know all about).

Got all that? Since the rate of polarization rotation is know, you can
set things up so that a wave travelling one direction will pass through
just fine while a wave in the other will just bounce back. This is the
non-reciprocal behavior that requires the "magic" material.

During World War II people thought that it was theoretically impossible
to make such non-reciprocal devices, though they sure would have been
handy for radar, etc.

I have never heard of a circulator for HF freqs. I imagine that, if
such a thing existed, it would be very large.

Gary and interested CCW people:
You are right on regarding the contribution of CCW to the weak signal art as well as the change in effort due to the use of small computers. There is a very large number of experimenters using CCW and an even larger number using more advanced correlation techniques and slower speeds. The transmission method is Biphase or Differential BPSK usually at the one to three character per second speed. In more direct answer to where to get additonal information: A bibliography is being assembled by Pete Eaton, WBFLW eatonp@eniac.ac.siue.edu
Of greater interest to most is the effort of Bill DeCarle, VE2IQ who has for years written programs for CCW that can be run on reasonably fast IBM computers. The DSP portion of the system is based on his "sigma-delta" audio spectrum analyzer published in the Jan 1992 QST. Even more complete discription have appeared in QEX and "RADCOM" in the UK. For the individual asking in Germany, a complete program using the DeCarle techinques but more user friendly is available from DJ7HS, Ernst F. Schroeder, Pinkenburger Str. 25 D, D-30655 Hannover, Germany. His program is called PCW for precision CW. Ernst's program is for CCW only. DeCarle continues to write highly advance decoding schemes and make available software and hardware for both CCW and BPSK. His address is: Bill DeCarle, 29, Sommet Vertical, St.Adolphe D'Howard, QC, J0T 2BO, Canada.
As mentioned previously, the Digital Digest has a column with CCW news which is used internationally. Comments regarding BPSK is contained each month by amateur contributors such as myself and other experimenters. If all else fails listen "thirty five up" kilohertz on all the ham bands as this is convention used by CCW and BPSK experimenters. CCW sounds just like 12 WPM CW only very precise, so ears still make a most satisfactory decoder. Do join us. 73 Cliff Buttschardt W6HDO

How about a lumped element version of a coaxial ratrace? That
has properties similar to a circulator without the need for the
ferrite material. I'd expect the achievable isolation would be
insufficient for this application, however.

Gary

A suggestion that has worked well for me in audiophile applications:

Connect the two electrolytics of the same capacitance value back-to-back with the positive sides together. Place a 100K-ohm resistor at this junction and the other end of the resistor to a high supply rail not exceeding the working voltage rating of the capacitor (e.g., +12VDC is fine).

Depending on the circuit's configuration, the 100K resisor in effect biases the capacitors properly. Try it and get back to us!

When I was young and foolish, I looked into the possibility of a circulator
at a "low" frequency such as 28 MHz. There are papers written about so
called lumped element circulators at frequencies as low as 100 MHz. They
consist of a hockey puck size piece of ferrite with 3 windings around them
at 120 degree angles, with a big permanent magnet to bias them. The basic
problem with going to arbitrarily low frequencies is that the magnetic bias
required is proportional to frequency, but there is a "low field loss"
phenonmenon which you are stuck with for the low fields used at "low" frequencies.
(Low vs. microwaves). The impedance matching to the coils is a conventional
circuit design problem, but it is going to be fairly narrow band and lossy
no matter what you try to do. You also don't get a hell of a lot of isolation
maybe 10 to 15 dB. The ferrite does need to be a special type like YIG with
so called "gyroscopic" properties; you can't use the ferrite you would typically
use at 28 MHz, such as Fair-Rite #68 nickel-zinc ferrite. If you want an
interesting, non-practical, project, you might see what you could do at
28 MHz. You can probably get some degree of circulation going.

To make a passive circulator, you need a non-reciprocal circuit element.
Coils, transformers, resistors, capacitors, etc. are reciprocal. Some
ferrites are non-reciprocal as are hall effect devices, although hall
effect devices are not really passive. There have also been papers
describing "active" circulators using opamps, but 28 MHz is too high for
that (even with 1 GHz. op amps).

If I may jump in, No he doesn't. It's not the total power that counts, it's the power at each frequency (+8).

It is very refreshing to finally see someone who has something
constructive to contribute to this thread. Thank God that the previous
brown-nosers decided to take a powder!

The National LMX1501/1511 is also a suitable device for the ap-
lication, and is comparable to the Philips devices noted above. Unfor-
tunately, in this country, the Philips products are getting harder to ob-
tain, and I've pretty much dropped them from my preferred vendour list.
Now, I usually use NEC for discrete devices. Philips makes a large num-
ber of devices that are ideally suited for good quality receiver design,
but the devices are not readily available. I can get samples and purchase
small quantities of NEC material any time I want from CEL.

There is nothing at all wrong with striking out on your own and
learning by way of your own mistakes.

Hi,

Well it looks like we're all space cadets now! ;-) Just kidding.

That's correct Tom. The ground system has two functions. To provide a low impedance to "push against", and to stop field coupling to the lossy media below the ground system.

OTOH, the "image antenna" is simply a tool for pattern analysis. The current represented in the image antenna does NOT really exist in that physical location of space, and it does NOT provide a reference impedance (if it did the input impedance od a quarter wave resonant vertical would be around 60 ohms). It is an imaginary source that represents the earth (or reflective media) SURFACE currents for many wavelengths in each direction from the radiator.

> Think of it as a valve which turns on when the drive exceeds the threshold.
> If the valve only turns on for a small fraction of a cycle,
> you won't get mch water (signal) through it).

A related question, how does the duty cycle (if not exactly 50 %) affect
the dbm performance (particulary spurious response) ? If the oscillator or
buffer clips the other half-wave of the sine-wave a bit, the zero crossings
in the AC-coupled LO-port no longer happen at exactly 0 and 180 degree,
thus changing the duty cycle.

Should the LO-injection be low-pass (or even band-pass) filtered to
restore perfectly equal duty cycle?

How would this affect mixer performance, when the leakage from the
RF-port to the LO-port will find something that is radically different
from 50 ohms resistive. Should the low-pass filter at the LO-port be
T- or pi-configuration representing a high resp. low. impedance for the
high frequency leakage from the LO-port.

Hi Guys,
In an earlier post I asked the question "don't you mean two +5dBm tones?". Someone responded that this was
wrong and that it is only important to consider one of the tones. Alas, my news server seems to have dropped
my post as well as this one. First, if the manufacturer of the mixer is stating the intercept point they are
referring to the total power at which this occurs. Why? Lets ask this question....what would be the
performance of the mixer with two tones of uneven power? What would be the performance with a complex signal?
Sure, when you perform a "two-tone" test on a device you might measure the intermod rejection from one of the
input tones to one of the third order products. What do you do if one of the third order products is smaller
than the other? How do make this information useful? You have to consider the total power. Therefore, if
the intercept point occurs at +8dBm then the manufacturer must have been using two tones of +5dBm each.
Otherwise, the powerlevel would have been correctly stated as being 3dB higher. Of course, any of you who
have performed intermod measurements would know that the manufacturer used tones which were much smaller than
+5dBm each while measuring this mixer!

>theory and practice.

I had to dig around a little to find my class notes on Gilbert cell multipliers. After blowing off 18 years of accumulated dust, here is a brief summary of three different ways to apply them.

1. If the input signals are kept small enough, the multiplier acts as a true linear four-quadrant multiplier. The output is proportional to the multiplication of the two inputs.

2. Increasing one of the signals to large enough levels essentially "squares it up", and you end up multiplying the low level signal by a square wave. This is similar in concept to the diode ring mixers previously discussed on the list. The advantage here is that you maximize your conversion gain, although with the disadvantage that you produce mixing products with all of the square-wave's harmonics.

3. The third application of the Gilbert cell mulitplier is as a phase detector. In this case both inputs are run with high level signals, and the output is a square wave (functionally, this operates just like an XOR gate).

From Roger's description, it sounds as though the SL6440 is operating under the conditions described in "1" above. That is, if we are multiplying sine by sine, we'd expect the sum and difference

products related to those two signals, and minimal (as spec'd by the multiplier) distortion products. However, if one of the signals is "pre-distorted" (unfiltered, in this case), then we should see sum and difference products with all of the harmonics too. In Roger's case, the level of the unfiltered LO's harmonics were "down very little" from the fundamental, so the product terms with these harmonics should also be down very little, which is consistent with Roger's observations.

If we were operating in case 2, then I'd expect the level of the harmonic product terms to be the same, irrespective of input filtering.

Someone on the list may have a data sheet for the SL6440 -- what levels do they recommend for the inputs? And do they discuss the multiplier's operation (is the LO signal "squared up"?).

- Jeff, WA6AHL

By the way - for those interested, there is a good analysis of Gilber Cell Multipliers in the book "Analysis and Design of Analog Integrated Circuits", by Gray and Meyer (published by Wiley).

>
>73,
>
>Jack WB3U

That's a tough one Jack. There are too many variables to give an exacting answer.
The higher the field density at a given lossy surface, the more power lost. The power loss can come from both electric and magnetic field effects.

Horizontal antennas generally have less loss because they're often placed higher above earth, "fields" are less concentrated. Even the performance of fairly high dipoles can be enhanced by adding counterpoise wires. A low dipole's performance can be greatly improved by adding counterpoise wires.

An end-fed vertical *always* requires some form of electrically neutral mass to terminate one feedline terminal. That causes additional system I*I R losses, or even power loss by direct radiation.

A base fed half-wave vertical has this problem, not quite as bad as a quarter wave vertical, but the loss is still there. That's because the base impedance of a practical half-wave vertical isn't infinite (for a thick radiator it can be a few hundred ohms).

All half-wave verticals (even center fed) have strong electric fields at both ends, that causes E field losses to predominate near the base. But they also have magnetic field losses.

Hi Murray... Thanks for your comments.
One chip solution eh !?!? What do you mean by this ? Do you mean it has
a built-in VCO, requires no external programming chips ect... :)
or do you mean that no external prescalar is required ?

My latest scheme is to use the Motorola MC145170p. This one is rated
for 160 MHz, serially tuned. I got a few samples from Motorola and
should have no trouble getting them in small quantities from a local
dealer. It's avalaible in DIP or surface mount package.
Minimal change in my firmware to change from the '157 to the 170 for
programming it. Obtaining Phillips parts around here is not easy...I
guess you work with whatever is available !

Regards! Hugh Duff VA3TO

>my post as well as this one. (snip)

Hi guys,
I was wrong and the following message from Bill Sabin jarred me back to reality! Here is
what he "VERY
correctly" had to say on the subject!

The IIP3 is specified in terms of two equal tones as a matter of
custom so that everyone knows what the standard conditions are.
If the IIP3 is specified at +8dBm, then each tone is +8dBm and
at that level the IMD products would also be +8dBm if the mixer
were still linear at that signal level. By linear I mean that gain
compression has not occurred. But because the mixer is not linear
at that input level the test is performed at a lower level where
the mixer has not yet gone into gain compression. For example
they might use -10dBm per tone. The IIP3 is then calculated from a formula
IIP3(dBM)= SIG(dBM) + 0.5*S/D(dB) where SIG is the level/tone of the
two equal test signals and S/D is the ratio, in dB, of each signal to
each distortion product. The IIP3 value is the level of each of the
two equal tones. Page 17.6 of the ARRL Handbook 1995/1996 editions
gives a discussion that gives more details. If the tones are not
equal then some special mathematical analysis is needed which I
will not have time to get into.

Thanks Bill

my apologies for any confusion I may have caused!

: B comes out terminal C, and energy fed into terminal C comes out terminal A.

I can't explain the theory but it's a sandwich of three metal discs and two disc-shaped magnets. The strength of the magnets has everything to do with the frequency at which it will pass RF. The size of the magnets has everything to do with how much power you can pump through it. Like anything involving a magnet, it is prone to saturation when high powers are involved. Most professional isolators (Celwave, Sinclair etc.) can handle 150Watts+. Typical insertian losses for single-isolators are 1dB.

They are available for any frequency band.

: I am trying to connect a transverter to a HF radio (TS-50) without a

Hallo everybody,
Is there anybody who knows how to modify a Alinco DR-599E VHF-UHF transceiver (it's the European version of the Alinco DR-599T) to enlarge the RX range to the air bands and the civil bands in VHF and in UHF and to the 900 MHZ band?
Thank you, and, please, send the answer via mail because I cannot check the newsgroups so often:)

Gentlemen,

I recently acquired a beautifully constructed receiver at a local hamfest.
I recognized it immediately as a version of the HBR series of receivers that
were described in QST in the sixties.

Unfortunately my copies of QST from that era were lost some time ago.
I would like to track down info on this receiver. I know there were many
versions and articles. Can anyone help?

Thanks, Wes -- N7WS

5073. The VHF/UHF DX Book is back!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-06 00:00:00 UTC
From: Ian G3SEK <G3SEK@ifwtech.demon.co.uk>
Message-ID: <688139122wnr@ifwtech.demon.co.uk>
Source record: 109734

'The VHF/UHF DX Book' will be available again from December 1st.
The second printing includes some minor typographical revisions and
an updated version of G4DDK's 'Suffolk' 28-144MHz transverter.

RSGB will be handling all distribution, but expect delays of some
months before the book is available from national distributors such
as ARRL. In the meantime, anybody, world-wide, can order direct from
RSGB.

Their phone number is +44 1707 659015, although fax is obviously
cheaper and more accurate: +44 1707 645105. The mail address is:

RSGB
Lambda House
Cranborne Road
POTTERS BAR
EN6 3JE
England

The price is 18.00 UK pounds (under 16 pounds to RSGB members).
Insist on airmail, because surface mail takes forever. I believe
that airmail for a single copy is under 3.00 pounds. Currently
1 UK pound = about $1.50-1.60.

RGSB accept all major credit cards. As far as I know, the exchange
rates on credit card transactions are very fair, so credit card
looks like the best way to order.

73 from Ian G3SEK Editor, 'The VHF/UHF DX Book'
'In Practice' columnist for RadCom (RSGB)

[Note that I have no direct commercial involvement with the
distribution of the book: this message is for information only.]

What is the max. difference in timing on this signal when the two
stations are ~300 miles apart? How variable is this? If I compensate
for the difference in propogation how much will the propogation vary
from minute to minute and day to day?

>rep. all it needs to do is id and time out.

I like the RC-100 by MCC. They are about $150 and are very versatile. You could actually install rx's on 2 bands at the same site, voice ID's the link, cw id the link, and have full remote control of the link (which is nice when you're trying to figure out where a problem is sometimes, heehee). You can also program a beep on your link tx back to the main site to id it as being a signal from the remote.

73 de WB4IUY

PS...Micro Computer Concepts advertises in the ham mags with an add for their full blown controller/patch for $249 or so.

There is an excellent publication called "Towers International Transistor Selector", which I believe has just been updated. It is published in the UK and is available from Maplin Electronic Supplies in Essex, England, phone 011-44-1702-554161.

I have an older version of the book and I'd be more than happy to look to look up some specific numbers for you, let me know.

Here we have a common misconception. A rat-race hybrid, or for that matter any kind of hybrid, power divider, or directional coupler, whether lumped or distributed, coaxial or waveguide, is a reciprocal network. By definition, reciprocal networks have no isolation. What does "reciprocal" mean? It means that the insertion loss for a source connected to port A driving a load at port B is the same as the insertion lost for the same source connected to port B driving the same load now connected to port A. (This is true for all commonly used definitions of insertion loss, such as Z12, Y12, S12, transducer gain, what have you.) For networks with more than two ports, it is true for any pair of ports, assuming the terminations of the other ports don't change when the source and load are swapped. In a 3 port circulator, a source at port A ideally puts all its power into a load at B and none into C. Moving the source to port B puts all the power into port C and none into A. This is non-reciprocal behavior.

I don't remember the years, but the ARRL handbook published a
transmitter they called the Cubic Incher, I would guess about the 1985
timeframe. It was a cubic inch in size, and I beleive 1 watt output.

Also a very simple single conversion receiver can also be constructed
using a crystal for the LO, greatly simplifying the circuit. I beleive
a Popular electronics about 5 years ago had the schematics for this.

Sorry I can't be more specific, I made a great sacrifice, We have a
foreign exchange student from Paraguay and ALL of my reference material
is stored for the year along with most of my test gear.

Has anyone out there received satisfactory results with the Ramsey FX440 transceiver kit? I built one, but once completed, I noticed a plethora of ploblems. For instance, the microphone amp not working, the VCO being VERY susceptable to 'mechanical' noise (i.e. touching the board with an insulated tweaker), no power out, and lousy sensitivity. I thought I did a pretty decent job assembing this thing, but either I'm WAY off in my assembly techniques, or the kit's not what it's cracked up to be. I'm going to start troubleshooting the rig this week (I hope), and will keep any interested parties up to date.

I knew I'd get a response like this just as soon as I posted. What
I meant is that for the application he has in mind, a lumped ratrace may
give him the virtual TR switch he's looking for. I understand the ratrace
isn't one way like a circulator. Sorry if what I wrote above gives that
impression (and I can see how it might). That's not what I was trying
to say. A ratrace can offer adjacent port isolation due to the relative
phasing around the loop. And if I read what he's trying to do correctly,
that's what he really needs, not the non-reciprocal action of a circulator.

Gary

5100. Spec Analyzer + Noise Gen = Tracking Generator?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-07 00:00:00 UTC
From: john.ackermann@daytonOH.ncr.com
Message-ID: <john.ackermann.407.000B9A96@daytonOH.ncr.com>
Source record: 109761

Sorry if this is a bit long, but in addition to posing a question this might be useful info for other folks.

If you can't have a network analyzer for tuning cavities, the next best thing is a spectrum analyzer with a tracking generator. Of course, such things aren't cheap.

I'd always wondered if a noise generator could serve as a signal source for cavity tuning. If its output is relatively flat over the narrow range you typically look at, you should be able to see the bandpass characteristic very nicely.

Well, at Hamvention last year, I got an answer. The Advantage Instruments people were selling their spectrum analyzer with a tracking generator option for only $100 extra. I asked them about it and discovered it was, in fact, a noise generator! The gen is supposedly flat to 1500 MHz.

They were willing to sell the noise generator module separately, so I ordered one. And, I finally got my Tek 491 analyzer back from the shop and was able to play with the combination a little bit last evening. With the video filter in line to smooth out the noise, and with a slow sweep speed, it did work!!!

Well, pretty much, anyway. I was able to look at some helical resonators and see a very nice passband, and do a good job tuning them. On the other hand, attempts to look at notch-type devices (a couple of notch only duplexers) didn't work at all. I could get all sorts of bumps on the screen, but couldn't see anything that looked like a notch.

Also, I noticed that the analyzer showed some dips -- including one very large one near the left edge of the display -- that didn't move with tuning. I don't know if these were image responses or some other spurious signal. I suppose that the mixing products from a broadband noise source could be interesting!

Anyway, I wonder if anyone else has experience with this sort of lash up, and any advice on how to make it work better -- particularly how to look at notches. My first guess is that using 50 ohm pads on both the output of the generator and the input to the analyzer might make a big difference by ensuring that the cavity is seeing the right impedance.

Does anything need to be done to an ordinary pass-band cavity to use it as a notch cavity? It seems "obvious" that a tee connector on one of the connectors would do it, but is it that simple? Does the other coupling loop need to be terminated -- if so, into 50 ohms, or a short? Any magic length for the cable between the signal source/sink and the tee connector?

Thanks and 73,

Hi John! I've had very good luck by removing one coupling loop and plugging the hole with a metal disk. Change the remaining loop to approx. 1/10th wavelength, and tune for notch. Position the loop so that the "cold" end is towards the 1/4 wavelength center stub.

Hopw that helps.

that is exactly what I was about to say! I've had similar problems with notch cavities and found that 50 ohm pads will do the trick.

I build a lot of my own cavities, including bandpass cans. I prefer notch cavities, hands down, if my stuff is gonna be at a fairly clean site.

>73..Jim

I have seen them used in fragile 900 MHz (cellular base station) power amplifiers. The power amplifier output goes into port "A" and comes out port "B" which is connected to the load (basically, the antenna). In the case of mismatch, power reflected from the antenna is reflected back into port "B", which then appears at port "C", which is a 50 ohm dummy load.

End result? Said fragile amplifer transistors are protected from SWR problems.

Another extra (although not too interesting): it limits the amount of RF reflected to the amplifier, thus limits the SWR. Useful for high power units.

Hi,

I have been experimenting with low power UHF/microwave oscillators and amplifiers and now want to increase the power level that I am using. Most of these experiments were with wideband, low power devices (BFR96S, BFG34 etc) which are inexpensive and easily obtained. What I would like are some suggestions for medium power (1-5W) UHF transistors that are cheap (I will probably blow up several of them!) and readily available. I was wondering what cell-phones use for the final stage - presumably cellphone transistors are relativly cheap and common (unless of course they use a hybrid module for the PA). Any suggestions ?

Jim:

There are several applications. Among them:

1) Most radars use one as a pseudo antenna changeover relay. The transmitter output drives port 'A' and appears at the antenna connected to 'B'. During the transmitter pulse, some energy still appears at port 'C' due to imperfect isolation and antenna SWR. This is usually additionally attenuated by some type of limiter. Today, these usually use self-biased PIN diodes. During receive, signals from the antenna circulate to port 'C' which is connected to the receiver input. In the case of poorly balanced mixers (not common these days) LO leakage, which might "give away" information to potential jammers can be surpressed by another circulator used as an isolator (see next item.)

2) A circulator with port 'C' terminated will act as an isolator. If a signal source drives port 'A' and a mismatched load connects to 'B', any reflected energy from the load will circulate to port 'C' and be dissipated. Therefore, the signal source sees a "perfect" load, regardless of the actual reflection coefficient of the load. Isolators are often used to protect delicate amplifiers from the effects of things like arcing waveguides or the pilot of a fighter plane turning on his fire-control radar while still in the metal hangar. These are often water-cooled!

3) A circulator with an adjustable short on port 'B' will act as a phase shifter. A signal into port 'A' appears at 'B' where is sees a 100% reflection. The reflected signal circulates on to 'C', delayed in phase by two times the length of the short.

4) In some reflection amplifiers, a circulator is used for interstage coupling. A reflection amplifier is really an oscillator that is injection locked to a lower level input signal. The injection signal is input to 'A', circulates to 'B' where it drives the locked oscillator. The output from the oscillator circulates to port 'C' which is the output. This process can be repeated with additional higher power stages. One missile I am familar with uses three IMPATT amplifiers, each driven in this fashion.

These are some of the applications I am familar with. Hope this has
been informative.

the bridge itself >is accurate enough? >Any suggestions are most welcome.
>72,999 de Kari OH6BZ

Kari, see if you can get a copy of; "Build this L-C Checker" by Jack Najork, W5FG in Ham Radio (USA) Dec. '88. Jack uses a Colpitts oscillator, to which are applied your unknown coils and capacitors. If you have access to a frequency counter (or another calibrated receiver), you should be able to match components to well within 1%. Use this simple formula;

CpF = 25330 divided by (frequency MHz squared X LuH), and

LuH = 25330 divided by (frequency MHz squared X CpF).

73, Drew, VK3XU.

From: wdr@world.std.com
Message-ID: <DHqvz7.2pJ@world.std.com>
Source record: 109777

The brochures on DeOxit and ProGold, from CAIG labs,
sound good. (They sent 'em after I'd seen their ads in QST etc
and requested 'em.)
What experiences have you all had?

A cleaner that will take corrosion off of batter terminals
would be great; the number of toys, radios, flash-lights
with blue-green battery contacts is embarrassing. It sounds
like that's one of the uses for DeOxit. It makes sense to me
that there should be some solvent that dissolves CuOx and
similar corrosion product; I'd been wondering what to
buy. Is this it?

But what about the claims for ProGold? It says it re-bonds
the plated surface if any to the original metal and prevents
corrosion; it claims that intended signals pass through it
via quantum tunneling but that it acts as an insulator to
corrosive currents? Does that make sense? Does ProGold work,
or just gunk up your connectors?

Sign me, hopeful but skeptical in Boston,
73 de N1VUX

I think it should be a 2N3906 PNP instead of the 2N3904 (how I would
have done it). You could also use the 2N3904 if you reversed
the emitter and collector.

>2) The VFO inductor L1 has a tap, but there doesn't appear to be any

Typically, tapping 1/3 the way up usually works. (8 turns) Tap up
higher if you need more feedback--closer to the ground for less.

A similar use is made in the Motorola UHF Micor radios. The finals there were early solid-state UHF devices that were more than a bit fragile, and to protect them from VSWR Motorola built a circulator into the antenna switch. Neat design -- the antenna relay switched the C port between the receiver and a dummy load.

5124. ? PLL VCO TECHNOLOGY ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-08 00:00:00 UTC
From: tom.alldread@minfox.com
Message-ID: <9511081820167755@minfox.com>
Source record: 109785

Greetings:

I have been reviewing the technical data on the National Semiconductor LMX1501A frequency synthesizer chip. Does anyone know of companion VCO chips? The documentation suggests that muRata and M/A Com manufacture a line of VCOs compatible to the LMX1501A. I wonder what VFO frequency ranges are available and if there are any that operate in the 10-100 MHz frequency range?

The literature suggests single chip VCOs are available in a surface mount package that operate in the 800 MHz range. The only external components are for the loop low pass filter. The oscillator gain block, resonant components and varicap diodes all appear to be contained within the chip. A VCO is shown on one block diagram that is designated EX934. I wonder who manufactures this chip and what frequency range it covers? Apparently it is not a National number.

Thanks in advance for any information that sheds light on the current VCO technology.

In a previous article, THOMAS STICHELBOUT <stichelt@esiee.fr> wrote:
->when energy coming from a goes to b through a circulator,
->in a 3 way terminal, it won't go on the way c, which will be isolated.
->It used for receiver : Imagine an antenna which is plugged on way a, a
->receiver
->on way b , and ground on way C. You don't want your receiver to emit anything
->on
->the antenna. Therefor you use a circulator : All the energy coming back from
->the receiver will go to the ground and not on the antenna, which is "isolated
->from the receiver" Is that clear enough ?
->If you want to know some more about the subject, try to read books dealing
->with
->hyperfrequencies techniques...
->
Eh.., hm... well, this example is ok, but it's not very often when you worry
about reciever emmitting anything back to antenna. Besides, you can't really
get rid of RF by grounding it. You'd need to put load there. The lot more
common application is when you have tranmsitter and reciever using same antenna
and you want to make sure that transmitted signal going into antenna only,
and recieved signal from antenna going to reciever only. So, you connect
transmitter to port a, antenna to port b, and reciever to port c, you'll
get signal from transmitter (port a) going to port b (antenna) and nowhere
else, and recieved signal from antenna (port b) going to reciever (port c)
and nowhere else. Another application would be when you want to protect
transmitter from load mismatch and isoltare reflected signal from forward one.
Actually, in all of these examples you can use hybrid as well...

Mike.

If you believe CAIG's claims, I can find a distributor for "Co-ax Grease,"
that miracle substance of the 1970s that kept SWRs from clinging
to your feedline.

I'm no longer a QST subscriber (not because of the quality of the mag
or the ARRL, I should mention) so I haven't seen the ads -- QST does
have a policy of not accepting misleading or deceptive ads and I'm really
surprised they took this ad.

I know it's hard to check out every product and every ad in a magazine.
How about one of the ARRL people who's a frequenter of this newsgroup
following up on CAIG's claims of "quantum tunneling" and preventing
"corrosive currents"?

Since it's not April, I know you're looking at a paid ad.

Jim N6OTQ

Ken,

Why on earth do you need an antenna tuner for 2 and 1.5 m??? All antenna tuners introduce SOME losses and on VHF frequencies you want to minimise these..... There have been tuner designs but If I were you I would try to correctly set up my antenna system in the first place and not rely on a tuner to "fudge" the system to resonance.

Cheers,

Al Bolton.

5136. Re: What's circulator good for? was Re: How does "circulator" work?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-09 00:00:00 UTC
From: joeld@sr.hp.com
Message-ID: <47tr6h$p8k@canyon.sr.hp.com>
Source record: 109797
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics

On circulators: These are non-reciprocal devices that work by the fact that the magnetic field propogation is different in different directions. You might think of it has having one phase shift (say 15 degrees) propogating from right to left, but a different phase shift (say 75 degrees) propogating from left to right. The circulator takes advantage of this to cancel signals in one direction, (say port 1 to port 3) but add them in another (port 1 to port 2). A hybrid does the same thing, in a way, but depends upon the match at each port to maintain balance. Hybrids that I've seen cost at least 3 dB of power because of the matching requirement. Circulators can be perfectly matched on all three ports, and are still (nearly) lossless.

I have often seen circulators used as isolators (port 3 goes to a load) in order to protect transmitters. The output stage goes into port 1 of the circulator, port 2 goes to the antenna (which is usually matched to have a small reflection signal) and port 3 goes to a load. If an ice storm knocks off the antenna, the circulator routes the large reflected signal to the load on port 3.

For a very academic (mathematical) view, you might consult "Foundations for Microwave Engineering" By R.E. Collin. A different, though not less mathematical treatment can be found in "Microwave Engineering" by David Pozar. I think this is one of the best texts for engineers, as the derivations are complete, without the usual "skipping steps that are obvious (NOT)".

Joel D.

P.S. I saw an article in RF Design Magazine, maybe 2-3 years ago, by a sharp guy at (I hope I get this right) Comlinear, with an active circulator working up to the tens to low hundreds of MHz. All this if from my swiss cheese memory.

I'll bet these VCOs aren't single chips; they're almost certainly
hybrid modules, often about the same size as a 14 pin DIP. Admittedly
a minor point, but it could cause confusion when you're asking
a vendor about their VCO chips ;-).

5138. Mods for Icom IC-736

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-09 00:00:00 UTC
From: yingst@knighted.com
Message-ID: <47u3jh$les@crier.knighted.com>
Source record: 109799

Does anyone have any mods for the ICOM IC-736? I'm looking for a way to
turn the pre-amp back on below 1.6 Mhz.
Icom turns it off even though it the light says it's on.
I would like to listen for some lowfer stations 1750 meter band
(160-190 kc. 1 watt into a 50 ft antenna). I'm also looking for a way to
improve the recieve audio.
The recieve audio sounds flat and distant, lacking highs & lows.
With the notch filter ON the audio sounds a little better,
but it still could use some improvement.
They re-shape the audio through the notch filter,
and it actually has a nicer sound with the notch filter on
(Has more highs & lows).
I had a IC-737 that had the same problem with the audio,
just not sounding quite right. I am also interested in any other mods
for the Icom IC-736. Please send any replies to yingst@knighted.com Note:
If you post a reply into this newsgroup I proably wont get it,
my internet provider only holds news for 1 day. Thank You. Harry

According to the author, he bought a couple from Fair Radio
but they sold out. He said they are quite similar to the 312B4's
used in the Collin's S line.

However, the directional coupler isn't very critical. The one on
page 22.41 of the 1995 ARRL Handbook ought to work just fine.

Most surplus couplers ought to work as well, as long as they
are for the right impedance (might be some 75 ohm jobs out there)
and the right power level. You might have to reverse the diodes
if the output voltage is negative, or add 50 ohm dummy loads and
detector diodes, but this shouldn't be that challenging.

In: Oscillator Design & Computer Simulation by
Randall W. Rhea, Prentice Hall, ISBN 0-13-642513-5
He talks about using MMIC's in general and the MAR-3 as an example
for SAW oscillators. pg. 181.
This is a fairly high level book, but does include DOS based modeling
programs. I've used the "STAR" program included, and found it to be a
very good model of oscillator and related networks. It's not very easy to
use because it demands good input data, as S-Parameters or you have,
G.I.G.O.
A MAR-3 model is also included.
Suggest you try this only if you like working in the 100-3000MHZ range.

>about your basic approach to this.

What "unconditionally stable" means in this context is that no value of mismatch at an input or output port of the amplifier will cause it to break into self-oscillation. That's an entirely separate issue from a deliberate oscillator. Any amplifier with a gain of 1 or more can be made into an oscillator by feeding back the output to the input (through a suitable external frequency/phase selective network).

A big problem with MMICs as oscillators is their wide bandwidth. They tend to motorboat if you aren't careful, and have higher phase noise than is desirable too. MMICs are deliberately designed to be broad band, and that's an undesirable trait in an oscillator, or in a preamp where best noise figure is desired. You'd prefer the device to have less than unity gain at all frequencies other than the desired one.

MMICs are great as *buffer* amps following an oscillator, or as buffers following a good FET preamp where insensitivity to the following load impedance is an asset, or as post-mixer or post-filter amps where a broad band termination is desired, but they aren't so good as the first element of a preamp or as the active device in an oscillator.

A few months ago Electronics and Wireless World had an article on this.
I think it was by Ian Hickman, one of their regular contributors. I
don't think it was a particularly useful oscillator, however, in terms
of stability, purity, etc.

Well, unfortunately, the U.S.P.S. disagrees with you about the legality and the statistics professors out there at the University of Hawaii will be glad to tell you that chain letters require more people than the population of the earth to succeed more than a few levels.

Here is what the U.S.P.S. has to say:

ftp://garbo.uwasa.fi/pc/docs-net/chain.txt:

" FROM THE UNITED STATES POSTMASTER GENERAL:

Chain Letters

A chain letter is a "get rich quick" scheme that promises that your mail box will soon be stuffed full of cash if you decide to participate. You're

told you can make thousands of dollars every month if you follow the detailed instructions in the letter.

A typical chain letter includes names and addresses of several individuals whom you may or may not know. You are instructed to send a certain amount of money--usually $5--to the person at the top of the list, and then eliminate that name and add yours to the bottom. You are then instructed to mail copies of the letter to a few more individuals who will hopefully repeat the entire process. The letter promises that if they follow the same procedure, your name will gradually move to the top of the list and you'll receive money -- lots of it.

There's at least one problem with chain letters. They're illegal if they request money or other items of value and promise a substantial return to the participants. Chain letters are a form of gambling, and sending them through the mail (or delivering them in person or by computer, but mailing money to participate) violates Title 18, United States Code, Section 1302, the Postal Lottery Statute. (Chain letters that ask for items of minor value, like picture postcards or recipes, are may be mailed, since such items are not things of value within the meaning of the law.)

Recently, high-tech chain letters have begun surfacing. They may be disseminated over the Internet, or may require the copying and mailing of computer disks rather than paper. Regardless of what technology is used to advance the scheme, if the mail is used at any step along the way, it is still illegal.

The main thing to remember is that a chain letter is simply a bad investment. You certainly won't get rich. You will receive little or no money. The few dollars you may get will probably not be as much as you spend making and mailing copies of the chain letter.

Chain letters don't work because the promise that all participants in a chain letter will be winners is mathematically impossible. Also, many people participate, but do not send money to the person at the top of the list. Some others create a chain letter that lists their name numerous times--in various forms with different addressee. So, in reality, all the money in a chain is going to one person.

Do not be fooled if the chain letter is used to sell inexpensive reports on credit, mail order sales, mailing lists, or other topics. The primary purpose is to take your money, not to sell information. "Selling" a prod-

uct does not ensure legality. Be doubly suspicious if there's a claim that
the U.S. Postal Service or U.S. Postal Inspection Service has declared the
letter legal. This is said only to mislead you. Neither the Postal Service
nor Postal Inspectors give prior approval to any chain letter.

Participating in a chain letter is a losing proposition. Turn over any chain letter you receive that asks for money or other items of value to your local postmaster or nearest Postal Inspector. Write on the mailing envelope of the letter or in a separate transmittal letter, "I received this in the mail and believe it may be illegal."

> - Jeff, WA6AHL

Like most Gilbert cells, it's noisy as hell (compared to a diode
mixer) so you'll need a little RF gain ahead of it.

Unlike most it is rated to 150 MHz, and I've used it in a high quality
AM/FM tuner (for both bands!)

LO drive - 250mV rms (and give or take 6 dB, seems to make very little
difference, to linearity or conversion gain, so I think it's switching
at that level).

Input intercept point is said to be +30 dBm, and I can believe it.
To get this, though, takes a lot of power!

Hope thisa helps - Brian.

5152. ANNOUNCE: Al's Circuit Simulator version 0.19

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-10 00:00:00 UTC
From: al@atd.rochester.ny.us
Message-ID: <1995Nov10.174952.19564@atd.rochester.ny.us>
Source record: 109808
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.cad,sci.electronics.misc,sci.electronics,comp.lsi.cad

A new version of ACS is now available.

This release offers "improved" convergence.

Several new options have been added to control iteration damping.
In some cases, the program will take a partial step in an attempt
to tame the wild fluctuations that can occur during iteration with
Newton's method. This version appears to be considerably more
robust than Spice 2g6. Several test circuits that fail to converge
on Spice do converge on ACS. The cost of this is sometimes slower
convergence. It generally takes about 2 more iterations per step
than the previous version. This can be turned off, using the
"dampstrategy" option at a slight cost in robustness. See the
manual on the options command for more information.

login as "guest". No password is required.

ACS is a general purpose circuit simulator. It performs nonlinear
dc and transient analyses, fourier analysis, and ac analysis
linearized at an operating point. It is fully interactive and
command driven. It can also be run in batch mode or as a server.
The output is produced as it simulates. Spice compatible models
for the MOSFET (level 1 and 2) and diode are included in this
release.

ACS has several advantages over Spice, including:

The ability to probe just about anything. For example, you can get
a plot (ASCII) of MOSFET capacitance against signal input. There
is no need for dummy voltage sources as current probes. It will
show you when a MOSFET crosses a region boundary.

It is faster for large circuits, due to better sparse matrix
techniques and incremental update.

The code is more modular and easier to follow. This will help if
you want to study the source to see how simulators work, or add

your own models. The source language is C++.

ACS can continue after a convergence failure, leaving only a glitch in the plot.

Disadvantages compared to Spice:

No BJT model. Only level 1 and 2 MOSFET. Only Meyer's capacitance model.

Other missing features. (noise, pole-zero, ...)

5153. NEED HELP w/ SIMPLE AM SET-UP

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-10 00:00:00 UTC
From: you@somehost.somedomain
Message-ID: <47vug1$g4e@NNTP.MsState.Edu>
Source record: 109809

I need some fast help with an AM transmitter (in the 350khz range) and an AM receiver. This only has to transmit about 60-80 ft. I think I can handle the receiver, but I could use some help (i.e. a schematic) with the transmitter. Anyone with a simple sketch of this system could really bail me out.

Thanks.

I am not on 1750m but suggest you join the Longwave Club of America,
45 Wildflower Rd, Levittown, PA 19057. $18.00 per year. They publish
a monthly news letter that contains the kind of information that you
need. Also, you will find announcements of publications and BBS that
can help you. Check part 15 of the FCC rules. I believe unlicensed
folks are allowed 1 Watt into a short antenna about 30 feet; not sure
of specifics.

My current interest in LF is that I am a consultant to the ARRL and am
searching below 500 kHz for a piece of spectrum for a new amateur band.
The 1750m meter band (160-190 kHz) is being considered but it is too
early to tell if that will be my recommendation to the ARRL board.

I did operate LF in 1947 and 1948 before I was licensed in the Amateur
Radio Service. I had a lot of fun -- think you will too.

>is a spectrum analyzer with a tracking generator. Of course, such things
>aren't cheap.

>I'd always wondered if a noise generator could serve
[snip in consideration of bandwidth]

Hey, now THAT's a clever idea. But I've never seen a noise generator
that would put out enough poop to be seen on a spectrum analyzer with
any decent dynamic range left. How much poo did the noise generator
put out across the band? And what did they use for a noise source?
I've used zener diodes biased on the knee of the curve and gotten
enough excess noise to do NF measurements on receiver front ends, but
only down in the microvolt range. What you've found seems to be a
blowtorch diode that puts out significant fractions of a milliwatt.
Any answers?

Oh, BTW, Advantage also sells a $700 tracking generator that appears
to be a TRUE tracking generator out to 2 gig. I hope to get RF Design
mag to let me do a feature article reviewing their stuff in the next
six months or so.

5157. ** HELP with mic preamp

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-10 00:00:00 UTC
From: tgoins@accessone.com
Message-ID: <tgoins.17.003BA6DF@accessone.com>
Source record: 109813

Hi all,

I have a Heil Dual desk mic that I am trying to get to work with an Icom 735.
The problem is that the Heil does not provide enough output to the radio and I
have to almost yell into it with the gain turned all the way up to get any ALC
action at all.

So I went forth and built the high Z preamp from the schematic in the ARRL handbook.
It is a real simple circuit that uses a MPF102 FET as an amp. One problem
--- it doesn't seem to work. No output from the preamp at all.

Here is what I know.
1) The Icom 735 only has 8 volts available from the mic jack. The plans call for 12v.

2) The 8 volts is getting into the the circuit but the first thing it encounters is a 10K
resistor
which immediately drops the voltage a great deal. (is this resistor too big?)

3) I do not have an O-scope to check for audio in the circuit.

4) I built it inside of a metal box and I put panel mount mic jacks on both ends.
The components are built on single sided PC board. At this point nothing is
connecting the circuit board ground bus to the metal box. (should it be??)

5) I should have bought the Icom SM-8 instead of this Heil. You spend $100+ dollars
and it ought to work without this grief. :-)

6) I need some help.

Thanks,
Todd
N0MZT - Seattle

Folks, one very traditional and effective way to get a new USENET newsgroup going is to discuss the topic in a general newsgroup, then if the volume is sufficient, have someone go through the USENET new group creation procedure. In this case, the obvious general newsgroup is rec.radio.amateur.misc. If you have questions or discussion about ATV, post it there! Put "ATV" in the subject so people can find the posts. Should there be sufficient interest, I'll be glad to point anyone willing to do the work to the instructions on how to get the new group approved -- email me.

Some things to try:
1) Might be...see next. You might try a 9V battery for B+, which seems adequate for most preamps -- or kludge up a +12 supply (easy to do).
2) Can you put a 10K trimmer here, and experiment? This might be the fix.
3) Even a high-impedance analog voltmeter would help here. Say "AAAAH-DIO" to see a good signal. But not on the air!
4) You might have a ground loop, but if it were a problem you'd experience distortion, feedback, or maybe microphonics. Lowered gain is not a common ground loop side effect. Instead of suspecting the box it's in, you might re-heat all the solder joints, especially at the phone jacks, and make sure those are perfect. I've had bad connections to jacks before, and it was ^&^&^%%$@^ to diagnose, because the circuit worked fine when it was out of the box.
5) KISS. I like to buy _working_ solutions also. Could it be an impedance mismatch? Playing with an audio transformer might tell you something. You might even have a bum mic, though Heil has a good reputation for quality control. You might try swapping with somebody who has a known good Heil.
6) Experiment with component values, particularly those that provide the feedback loop for the MPF102. And don't be afraid to blow it up -- they're really cheap and pretty rugged, and you can test for over-dissipation with your fingertip. That's one way to know if you're moving in the wrong direction.

I'm not going to dis the handbook today. But I'd like to add that not every project in every circuit cookbook is going to work every time.

>corrosive currents? Does that make sense? Does ProGold work,
>or just gunk up your connectors?

That's nonsense. It can't tell the difference between a signal
electron and a corrosion electron. What it can do is keep
oxygen and water vapor away from a cleaned surface, and *that*
will prevent oxidation. Cramolin works better, but any high
dielectric oil will do.

Nor can it "rebond" the plating to the base material. The
resin used can sort of "hold it together" in the same sense
that a bottle's walls hold a liquid together. But to get
electrical contact, the fingers have to gouge through the
resin (the resin itself can't conduct or it'd short out
adjacent fingers). And unlike Cramolin, the gouge won't
flow shut when the connector is unplugged, so after a few
times plugging and unplugging you're back to an exposed
surface that can corrode.

>Actually, in all of these examples you can use hybrid as well...

He's right, Mike, circulators are used primarily for reverse isolation.
As you note, you terminate port 3 with the characteristic impedance.
You don't short it to ground, which does no good at all, and in fact
guarantees a reflection. In microwave work, it's common to have receiver
radiation since the receiver usually has a mixer as its front end and
can allow LO to leak back toward the antenna. The other major use of
a circulator is to isolate a transmitter PA from VSWR on the antenna
or from out of band components which may enter the PA from the antenna
and mix there to produce intermod which is then reradiated. The latter
problem can happen in a receiver mixer too. Circulators can minimize
either problem. Circulators are also commonly used to isolate an oscillator
from "pulling" by a following stage, and to isolate a driver stage from a
PA so that input tuning of the PA doesn't interact with driver output tuning.

Now a circulator as TR switch isn't too useful because the isolation
typically isn't that good, only about 20 db between port 1 and port

3. Since the transmitter typically puts out watts while the receiver wants to see no more than microwatts, the isolation is insufficient. You want something on the order of 60 db (or better) of isolation. A circulator can't give you that so you have to get it other ways. For transmitter receiver pairs operating on split frequencies, IE a typical repeater, you do that with cavity duplexers. For transmitter receiver pairs operating on the same frequency, the only real way that they can share a common antenna is by an active TR switch, either a relay or PIN diodes. A single relay typically only offers about 30 db of isolation due to capacitance through the NO contacts, but the relay can be designed to reduce that (rotary relays for example which rotate the open contacts 90 degrees to each other). But today, pi or Tee section configured PIN diode switches can offer up to 70 db of isolation, and that's plenty for most applications. And they're fast too.

Well, yeah, that's a good way to compare a circulator and a hybrid
for TR purposes, but circulators typically don't have enough port
1 to port 3 isolation to serve as a good TR in any case (typically
less than 20 db, hybrids are typically a little better at around
30 db). The primary use for a circulator is to take advantage of
it's unique reverse isolation. The hybrid can't offer that non-reciprocal
behavior. So you can protect a circuit from "pulling" by a following
circuit, including an antenna with high VSWR. And you can sharply
reduce intermod caused by signals entering the PA and mixing there
before being reradiated. Or you can reduce intermod generated in
a receiver using a mixer as the front end and reradiated back out
the antenna, and reduce LO leakage to the antenna from such receivers
too.

Circulators are usually mandated at multiple repeater sites to
prevent intermod from multiple signals mixing in PAs, or receiver
first mixer IM product reradiation.

>the rig this week (I hope), and will keep any interested parties up to date.

Note: my comments apply to both the 2 meter and 70 cm Ramsey kits.

Heh, I'm not surprised you're having problems with this kit. The failed
microphone amp is either a bad part or an assembly error (even Ramsey
can't screw up a simple audio amp). The microphonics are probably from
one of the crystal oscillators and not from the VCO. Did you mount the
crystals as recomended? That's very important.

The low output power is typical if you followed the Ramsey tuneup
instructions. You also need to use a spectrum analyzer when tuning
up because it's *very* easy to get lots of output power, but the
spectrum looks like a comb. I've found a point where good output
and clean spectrum coincide on the ones I've tuned, but there are
other points where they don't, so beware of using a simple power
meter for tuneup. You should be able to get a clean 3 watts out if
you muck around enough with the coil spacing for the PA and driver.
(The manual instructs you to wind them too close spaced to tune
up properly.)

You need to spread the receiver input coils *much* more than seems
reasonable to achieve good sensitivity. The turn to turn spacing
will wind up between 5 and 10 wire diameters when you have maximum
sensitivity. Ramsey doesn't like close wound coils (even though
the manual instructs you to wind them that way).

(You can make a tuning aid which will help you get the coils in
range. Take a wooden dowel and screw a steel screw in one end
and a brass screw in the other. If bringing the steel screw
near the coil increases output, you need to compress the turns.
If bringing the brass screw near the coil increases output,
you need to spread the turns a bit more.)

I haven't looked at a recent one of these kits, but early on the
transmitter was not inhibited when the synthesizer was sweeping
into lock. This can make you very unpopular with others on the
band. There's a lock indicator on an unused pin of the synthesizer

chip, and you can use that to qualify B+ to the driver stage through
a keying transistor. That'll keep it from kerchunking every repeater
on the band when you go from receive to transmit.

This will never be a great radio, but you can mod it to make
it an acceptable radio. Consider it a learning experience.

Remember those old GE "meters" found in power plants & other heavy-duty applications? They weigh 2 or 3 pounds, have gray-painted cylindrical bodies, usually have 0-1 MADC movements. The scale has 270 degrees, and may be calibrated in DCV, DCA, PSIG, or whatever. The thick glass bezel is 4" diameter, with a center hole containing a zero-adjuster. The bezel is framed by a 4 3/8" square black metal or plastic frame, held in place with 4 corner screws
I need a replacement glass bezel, with zero-adjuster. If you have one to spare, please e-mail me your price. Tnx a meg -- Frank Aldrich, WS0W, Boulder CO.

>
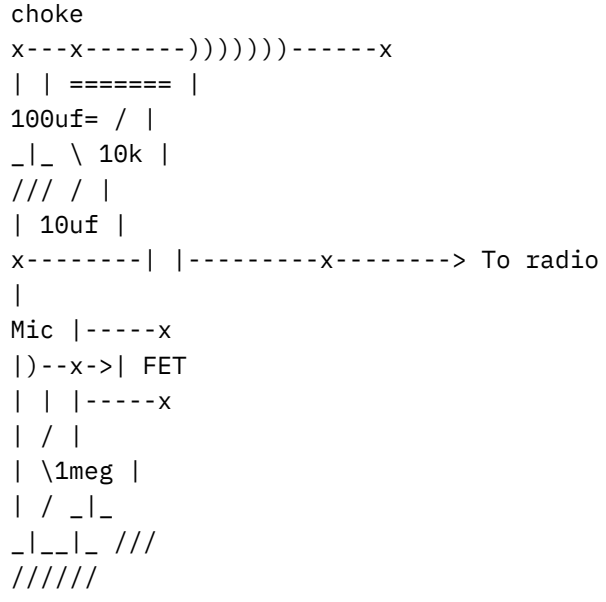
>2) The 8 volts is getting into the the circuit but the first thing it encounters is a 10K
resistor
> which immediately drops the voltage a great deal. (is this resistor too big?)

Well, not having found the circuit, I can't say for sure, but remember
you're phantom powering this circuit so the output circuitry should
look something like this:



The idea is that the choke supplies the +8 VDC to the top of the
drain resistor without shorting out the audio voltage fed back
to the radio. The 10uf coupling capacitor couples the audio voltage

to the line going to the radio. The 100uf decoupler is the PS bypass.

This is a far from ideal circuit, but it should work better than what you're trying to do. Ideally, you want the preamp to have about 20 db of gain and a 600 ohm output impedance. The typical way to do that today is with a BiFET opamp as shown in the current edition of the Handbook.

In any event, you won't have any output unless you separate the DC phantom power from the audio signal. In the circuit above, the choke and output capacitor do that.

I said: "I have a VIC 20 I want to trade for a IC-781" (how long do we have read thesre messages where some ham wants to trade his junk for something woth something).

From: KH2KQ@KA6EYH.#NOCAL.CA.USA.NOAM
To : K1OIK@KQ1K.MA.USA.NA

Hello Burt,

You actually got one of those VIC-20's you wanna trade?

I do not have a Icom 781, but I does have a Kenwood 950SDX - howsa bout dat?

Only problem is dat it am attached under the counter of a 36 foot motorhome. So if youse trade for da 950 youse gotta take the motorhome too. Its got a generator and only 123 actual miles. But the problem der is dat it am havin a dead battery and it can't start and it is in the driveway of my vacation home at the beach in Malibu - so youse also gotta take the house in Malibu if youse want the 950SDX.

Howsomever, there is a beach bunny and her girlfriend that said they would just die if I sold the Malibu house on the beach, so they come with the house and the motorhome and the radio.

If dat am OK, then weese got a deal!

Oh yeah, does the VIC-20 got a DC power supply with it?

By the by, if you hear of anyone who has a Kenwood TS-50 attached to a Mercedes 450SLC - I would like to trade a Radio Shack 202 for it!!!!!!!

To: k1oik@ccsnet.com
Subject: You hate good news.
Date: Fri, 15 Sep 95 03:42:54

they like threats. they thrive off of it. i don't agree with everything you have said, burt. however, you are right on about several issues... one of them being the burping, farting, pants sagging in the crotch from too many handhelds on a waist that can't support them... i may carry a handheld, cellphone, and a pager all at once, but at least i'm not so out of shape that i have my pants sagging like they have a load in them. i stay somewhat in touch with reality... i liked the rabbit story. it made a pretty damn good statement... that's why they don't respond. many of them know that to take away code would allow intelligent people, people with more intelligence <gasp> than they are, into their little good ol' boys club.

no, not all hams that learn code are like what you described, only about i estimate 85-90% are like that, drooling with 10 handhelds on their belts looking like they're on some sort of mind-altering substance (too much rf overloading of the brain tissue). my group of friends and i all dress like we're the nightclub crowd for the underground scene... leather jackets with studs, some of us have half shaved heads (i'm probably one of the few that look almost normal), nocturnal, hang out on numerous 440 and commercial band repeaters, play paintball, get (raise eyebrows) exercise (i ride my bike at least 10 miles every other day), play sports once in a while, i love snow skiing, and take plenty of time out of the radios to go to the movies, spend time with my girlfriend (who just happens to like listening to the scanners with me once in a while to all the fire and pd activity), go camping, party...

seeing "young" punks like myself enter into the hobby bothers the oldtimer whiners and complainers on the local 2-meter boxes and the old fart elitist jerks that hang out on simplex on 144.245 around the valley

here, badmouthing everyone and everything that stumble across them on their commute home. i think my area has the largest population of INACTIVE currently licensed hams of just about anywhere. many of these people are interested in the "technical" aspects of ham, get their licenses, check into one of the local 2-meter high level boxes, hear all the old farts on all day pissing and moaning about colostomy bags, get dissillusioned and put their gear away in the closet. it's pretty sad.

they're so afraid that their little club will be "polluted" with fresh knowledge and arrogance to their little rituals that they lash out at any attempt to break the mold.

>the log?"

>Burt, K1OIK.

Burt,

If you looked closely at what is being said, you will see that one ham asking another ham's name for the log is entirely different than asking the ham for his or her name.

In the first instance, I am clearly stating as to why I want your name..I do keep a log of my contacts. Also this information can be used for sending QSL cards. All of this is quickly said by asking for your name for the log. However, I guess I could say "I would like to know your name because I am a nice guy,, I am keeping a log, and I might send you a QSL card". Hmmmm, seems a bit to much.

Hams are very personable otherwise you would not have FM voice, AM voice, SSB voice, or even ATV.

>Actually, in all of these examples you can use hybrid as well...

I sure hope you've never tried what you just described. The tiniest reflection coming off your transmit antenna will fry your receiver, guaranteed. In fact you don't even need a reflected signal to do damage, the circulator will take care of that for you. Huh?? When you say "and nowhere else" you are assuming a *perfect* circulator. They don't exist (except in design simulation software). A small part of the signal presented to Port A WILL show up on Port C and drive right into your receiver.

You are correct though, in *theory* on how a circulator works. Any signal coming in Port A generally leaves through port B. Any signal coming in Port B generally leaves through Port C. And yes, any signal coming in Port C will generally leave through Port A. Hence the name.

The most common usage (as has been mentioned many times) is when Port C is terminated, usually in 50 ohms. (If this termination is "built-in" to the circulator you end up with a 2-port device called an Isolator.) Transmitted signals go in Port A and out Port B to the antenna. Reflected (and other unwanted) signals coming back down the antenna feed line, enter back into Port B where they are sent to Port C where they get terminated. Very little makes it back to the transmitter, so it is completely protected (or Isolated) from what ever impedance lurks on the other side of Port B.

>LuH = 25330 divided by (frequency MHz squared X CpF).

>73, Drew, VK3XU.

Another idea is to use an MFJ207 SWR analyser. By arranging the cap.
and coil in series and putting a 50R resistor in series too, the
reactance of the cap and coil are almost equal and opposite so that
all the MFJ207 sees is the 50R. It gives a very deep dip. The better
the q of the coil the closer to 1:1 you get.

As Drew says, get the frequency with a receiver, a counter, or better,
an analyser with the digital readout.

Give it a try if you can borrow the meter.

Cheers. Murray Kelly. vk4aok.

I wish I would have read these responses before spending a few days
looking at MMIC amps in an oscillator. What I found certainly agrees with
the posts, the only way a MMIC was stable and reasonably clean was when
the feedback path had level limiting and narrow band (hi-Q) feedback with
180 degree phase shift.

Let me see if I follow this correctly. To build a TR switch, substitute the receiver input for the dummy load in an isolator system.

Wouldn't an additional side benefit be "The transmitter will always see a low SWR, because the receiver dissipates all reflected power"?

Interesting concept.

Douglas Braun (douglasbraun@hol.gr) wrote:
: There is a nifty RF device called a "circulator". It has three terminals.
: RF energy fed into terminal A comes out terminal B, energy fed into terminal
: B comes out terminal C, and energy fed into terminal C comes out terminal A.

The trick to a circulator is that the magnetic field created by the permanent magnets causes the iron atoms in the ferrite to gyrate - wobble on their axes like the earth's summer/winter orbit appears to wobble if the sun was your reference point. All the iron atoms (or at least a large portion of them) wobble at the same frequency and in the same direction. This wobble is tuned (by magnetic field strength) to the frequency band required. The incoming energy aligns the atoms not only by frequency, but phase, too. The RF energy can't go against the field wobble, so it is forced to go around the circulator in only one direction.

I had this explained to me by a world-renowned microwave engineer in about one minute, and I know I'm not doing his explanation justice, but I hope it is understandable.

I understand how microwave circulators work, I'm a little mystified how you can get a VHF or HF band one to work. The field strength must be VERY weak to make the atoms wobble so slowly, and so thermal noise will not allow them to stay well aligned. To get good isolation on the reverse path, the circulator would need LOTS of ferrite between ports, MUCH more than would fit in a 3" cube. So, there is probably a trick here, which I don't know because I've never seen a circulator for lower than, say, L band.

Hi Burt! I really miss your *perspective* on amateur radio over there on
the RIME network.

: 1. What is the thinnest book in the world?
: What hams know about women.

I heard "Italian War Heroes" myself.

: 2. How does a ham take a bubble bath?
: He eats beans for dinner.

Yeah, I heard "How does a redneck take a......"

: 3. What's a ham's idea of foreplay?
: A half hour of contesting.

I heard "Brace yourself Martha"

: 4. How can you tell if a ham is sexually excited?
: If he's still breathing.

This one is very old......

: 5. How many hams does it take to change a roll of toilet paper?
: We don't know...it has never happened.

The version I head was "Men" and not just hams.

: 6. What's a ham's idea of helping with the housework?
: Lifting his leg so you can vacuum.

Once again, I had heard "men"

: 7. What does a ham consider a seven course meal?
: A hot dog and a six pack of beer.

Once again, I had heard "men".

Burt, you're gonna have to do a little better than this!

Cheers!

Andy

Burt:

Did it ever occour to you that meeting someone in person is differnt
than meeting them on the air? In my 15 brief years as a ham and SWL I
have never heard a conversation, amateur or commercial that resembled
one I would have with someone face to face.

I dont remember ever telling anyone I was talking to face to face that
their voice was just above the noise level.

Furthermore I dont expect my radio contact to use perfect grammar or
say and do the things I do in order to enjoy communicating with him.

By the way Burt, whats this got to do with building and experimenting
this is rec.radio.amateur.homebrew isnt it?

Regards,

Tim Hynde ka8ddz

[Author was]
[Posted on 12 Nov 1995 17:39:29 GMT]

I am planning a hiking and backpacking trip and would like to try portable packet ops via satellite. I am familiar with packet but have never done any sat work. Is it feasbile to do satellite packet in the field with a handheld and "portable" antenna? Any suggestions/advice would be much appreciated. Thanks.

Dick, there are many many hams operating in the 1750 meter band, not that they HAVE to be hams but they are as radio experimenters. You got good advice to examine the LOWDOWN magazine. There is many beacons in your area but usually none of them can be heard by simply jambing a piece of wire into the antenna input of an all band transceiver. It takes careful effort to sort out the noise from the signals that are there. Everyone is allowed one watt input and a fifty foot antenna rather than the thirty foot antenna first mentioned to you earlier. 73 Cliff Buttschardt W6HDO

Oops! I seem to have put my foot in my mouth here! Apologies to any I have upset or misled. The Philips chips I mentioned are no less '1-chip' than the Motorola units referred to by Hugh. At the time of my first comments, I didn't realise that the '157 was more than a counter. It seems that one of the Motorola MC145 series may be a good choice for me as I have had good reports from several people and there may be fewer supply problems than with Philips.

Cheers, Murray

5210. Help with Shack Grounding techniques?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-12 00:00:00 UTC
From: herbr@netcom.com

Subject: Help with Shack Grounding techniques?
Newsgroups: rec.radio.amateur.misc
Organization: NETCOM On-line Communication Services (408 261-4700 guest)
Summary:
Keywords:

I recently read an article regarding ways to ground the equipment in the ham shack. This article suggested using something called "Aluminum Flashing available at any home improvement store"

Well, I didn't know what "aluminum flashing was, so I went to the home improvement store. Seems that there are several things they refer to as aluminum flashing.

Some were long flat bars of aluminum in 8 foor lengths with widths from 1/2 inch to 1 inches or so.

Others were shaped in a L configuration with a width on each side of 1.5 inches or so.

Then, they showed me these flat sheets of 3 foot by 4 foot metal, that they said was also called flashing.

The sheets look interesting, since that would seem to provide a large surface area to use to tie the individual pieces of equipment to. It could be pleaced under the rigs, or on the back side of the rig tabel, but I don't know if that is the "best way".

I am just looking for a good technique to ground all of the HF equipment and accessories in the shack. By the way, the shack is on the second floor.

If you are familiar with "flashing" and or have any suggestions on the best way to ground the equipment, I would appreciate your comments. I live in any environment where I have to be extremely sensitive the RFI / EMI and I want to make sure I do everything on my part.

Thanks and 73's/

Herb - KG6OK

Source record: 109722

Hi gang,
Well my two cents.... While I follow and find it hard to argue with the thoughts expressed regarding square waves driving Mini-Ckts mixers, my experience argues against it. I have found in the many front ends I have built from HF thru SHF, that a *clean* sinewave LO gives better results. Using square waves, even ones from a current source, has produced *many* harmonics and spurs in the IF that can be a real pain to get rid of. A well filtered LO on the other hand makes for a more quiet mixer. I realize that the diodes will reek havoc with my sine wave, and make lots of spurs....Like I said I find it hard to explain, but I now use clean LOs in my designs.
Ideas?

Herb, the flashing that is referred to in these articles is a roofing
product. It is aluminun sheeting just like that used in small cheap
metal project boxes. It is usually available in widths from 4 to 24
inches and lengths from 10 to 30 feet. You will find it in rolls in
the roofing section of your building materials stores...

Oh, I see, the self-righteous calling the self-righteous self-righteous.

I've only been an amateur radio operator for 18 years and I would have to agree with some of the observations. But amateur radio is not the people who participate, but the act of participating. Yes there are some bad apples, but in most activities which concentrate a group of individuals with a specific activity, such as talking to each other on the radio, this is bound to happen. Unfortunately, we are not all as perfect as we should or could be, but I didn't get into amateur radio to join some perfect elite group, I got in because I found being able to communicate over thousands of miles, with a make shift antenna and a relatively inexpensive radio, pretty cool. Other people probably got in for other reasons. Sadly, I think a vast majority of amateur radio operators don't even know what the FCC part 97 reason for amateur radio's existence is.

Don't let the bad apples spoil the excitement that can be found in amateur radio, there is something there for everyone (wives/girlfriends too).

Here's an original idea here....

IGNORE THE ASS... KILL FILES ARE OUR FRIENDS

I added Burt to my killfile, and WHOA.. the number of messages my newsreader
thinks it has is about half what it was.

Now... if there is only a way of filtering out responses.

Geez, don't give him a clue! I've got a killfile that zaps all postings to more than 5 newsgroups, since anything that widely crossposted is always a waste of time. I had idly wondered why all the Burt followups had dropped off my radar, but was mainly just happy that they had. (I happened to trip over your posting while experimenting with a different newsreader configuration.) Burt, *please* keep on crossposting, it really helps me out.

(BTW, I also kill every post with a subject in ALL CAPITAL LETTERS. They're also uniformly worthless. Funny how these things work.)

>
>Gary

Thank you VERY much. This is some of the best advice i've gotten with my nasty Ramsey problem.

You were right about the mic amp, my mistake that one, put in an electrolytic backwards. As far as, and you used the term 'microphonics' being not familiar with the term I'm going to assume that is refering to the 'mechanical noise' I mentioned, the only oscillator xtal in the radion is solid as a rock. The noise is definately coming from the VCO.

The version of the kit that I have inhibit transmit when A: the ptt is down (obviously) and B: the PLL is unlocked.

I like the tuning aid idea, when I get ready to do final tuning I'm going to try that, as well as bearing in mind the comments you made abou coil spacing.

I'm not looking for a great radio, but I am looking for a learning experiance. If I can get a decent radio out of it, I can always asign it to packet and be done with it. :)

5237. DSP for the R2?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-13 00:00:00 UTC
From: rohrwerk@netcom.com
Message-ID: <rohrwerkDHzoC4.5uF@netcom.com>
Source record: 109600

In some conversation on another list and privately, some of us were musing about the possibility of a DSP for the KK7B R2 receiver design to handle audio quadrature, filtering, and maybe multiple modes.

My limited knowledge tells me it would have to be more advanced than the usual 8- or 12-bit processors in the garden-variety outboard DSP audio filters, maybe more akin to that described in the QST review of the Watkins-Johnson receiver, or the boxes Rohde described in his articles.

I'll do it if someone pays for my course work and a sabbatical from my real job ;-) . Seriously, is anybody able to take on something like this?

: John Seboldt rohrwerk@netcom.com / CW: It don't mean a thing
: K0JD... Minneapolis, MN / if it ain't got that swing!
: My R2/T2 station described in / Di dah, di dah, di dah, di dah...

>lrware@aol.com

There were some papers published about 5 years ago by Mike Driscoll at the IEEE Frequency Control Symposium about oscillators using MMIC gain blocks. Mike got some fairly good results, although they were not earthshaking. Independently of Mike, I had experimented about the same time using transistors with shunt negative feedback to build a 640 MHz. SAW oscillator for the HP 5071 cesium clock. (See my 1992 Freq. Control paper for details on the clock architecture.) The shunt feedback on the transistor was an attempt to make a "homemade" MMIC that would operate at low voltage and current (that's why I didn't use a real MMIC). Anyway, for that application, it was an outstanding idea. The shunt feedback changes the phase shift of the transistor from 270 degrees back to 180 degrees and greatly lowers the input and output impedance to about 10 ohms. This is another reason I didn't use commercial MMIC's, because they are designed to give 50 ohms in and out. In most oscillator designs, you want the impedance as low as possible, not 50 ohms (after all, you're not going to be driving 50 ohm lines anyway, so there is nothing significant about 50 ohms). The negative feedback was one of the reasons we were able to get over 1 kHz. of tuning range with a varactor. (Several SAW experts declared this amount of pulling "impossible".) The negative feedback also improved temperature stability to the point where is was no longer significantly affected by the transistor (which was an MRF9411). Try it, you'll like it.

Someone had mentioned that this technique didn't work with notch
filters. The reason it doesn't is that the wideband noise overloads
the mixer in the spectrum analyzer and fills in the notch. If your
spectrum analyzer has a really good dynamic range, you might be
able to adjust the attenuator just right and get away with it, if you
don't need to see down more than 40 dB or so. Otherwise, use a wider
bandpass filter as a "roughing" filter in cascade with the notch filter
to avoid overload.

Source record: 109603

Heh, can't resist throwing in my 2 cents worth. In my
experience the term "Unconditionally Stable" is a misnomer and
easily misunderstood. Invariably when you read the fine print
there are "conditions" attached to the "unconditionally stable"
claims. Whether with op amps or mmics such as the MAR-1, I
have found that they yes, oscillate actually rather EASILY
unless careful attention is paid to layout, input/output
impedances, etc. Whether they can oscillate at a particular
frequency of choice sounds a bit chancy according to my
esteemed colleague Mr. Coffman... I've never INTENTIONALLY used
one for an oscillator but have lots of experience trying to
tame mmic circuits acting as oscillators but designed as amps
:)

5241. Re: Ramsey FX440

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-13 00:00:00 UTC
From: Jim Devenport <jdevenport@lanl.gov>
Message-ID: <48803k$sif@newshost.lanl.gov>
Source record: 109604

I appreciate your comments on the FX-440. I had very similar
luck with the original FTR-146, i.e. having to distort the
coils massively to get optimized sensitivity out of the
receiver, etc, plus the audio/squelch can get irritating to
listen to since it goes in and out with a loud "pop" etc.
But the radio is FUN (to me) to use! Being able to dipswitch
in any old frequency and have it respond.... it gives ya all
kinds of ideas about controlling it externally with a PC or
other CPU...
And, I've been interested in the broad band coverage of the
FX440 for some time, just never got around to sending in the
bucks for the kit, and have been put off recently by all the
bitter experiences posted here. Your post reconfirms my
opinion that Ramsey radios are largely quite good in the
"maximum bang for the buck" category. No, they aren't as slick
as a good used commercially made radio, but they are better
than anything I could reasonably homebrew and design in a
decent amount of time. Plus, I like the Ramsey manual
philosophy. Building a Ramsey step-by-step IS an
educational experience, having built several Heathkits
and KnightKits (giving away my age here) in days of yore
I know the only education I got there was in how to
solder, not in how each stage actually worked etc.
Having marketed kits myself I am aware of the widely varying
(or non-existent) kit-building ability of the average Joe Ham.
It is difficult to buy parts alone for the price of the kits
marketed by Ramsey. And it CERTAINLY helps to have scopes,
spectrum analyzers, etc, available for such projects.
One way to tune up a suspect transmitter without a spectrum
analyser is to tune it up first for max power as stated in the
instructions and then re-do the transmitter alignment with a
narrow filter between the transmitter and the power meter
circuit. You'll invariably find much less power coming through
the filter. A simple stripline filter will do.

Message-ID: <4880ct$sif@newshost.lanl.gov>
Source record: 109605

I built the first Ramsey synthesized radio (FTR-146) and it
suffers from many of the problems listed, but I think it is a
fun radio to use, it's one of the smallest mobiles I own (I
built a custom PC board case for it that very snugly encloses
the radio). I just think its fun to use a radio I built with
my own pinkies, though it sees service mostly as a packet radio
nowadays as you state for a "worst case" use for it.

Source record: 109606

There's an electronics supply house in Kent, Washington which has
about fifteen of the Signetics NE602 mixer IC's. They do sell
onesy-twosy...for a price...in this case, $5.02 apiece.
They are:
Supertronix, Inc
18650 68th Avenue So.
Kent, WA
Phone: (206) 251-8484
FAX: (206) 251-5402

I've been buying from Supertronix since 1984 having been quite satisfied
with my purchases. They do offer quantity discounts when they have the
product in quantity. In the case of the NE-602, they only have fifteen.
Good luck one and all!

Stephen Lee, AB7HI

I too have had a reasonable amount of trouble with the FX-440. It seems
that they have a sawtooth output from the synthesizer that is used
after averaging to keep the transmitter on (if the PLL's not locked, you
probably don't want to be transmitting..) unfortunately the layout is
such that this sawtooth causes lots of noise in the (audio frequency
sawtooth) transmit audio path. Sent to Ramsey, but they couldn't get
rid of the noise. The noise precludes even 1200 baud packet.
I finally disabled the output from the Synthesizer, to effectively
enable the transmitter always. Now I only have to deal with the
weak mic audio and hit-or-miss PLL lock problems.

Theoretically, the design will work but...

A local mail order house here in Phoenix has these in stock.

NE602: $2.50 each.

Given a possible shortage, I just picked up 8 this afternoon
as I use these alot in my homebrew projects.

The outfit is called:

DC Electronics
P.O. Box 3203
Scottsdale, Az 85271-3203

Phone number: 1-800-423-0070 and 1-800-467-7736

They are a hobbist mail order house and as such will accept
small orders.

Minimum shipping and handling is $4.00......

Can someone explain the difference in sensitivity when dealing with a DC reciever v.s. a superhet or any other type of conversion reciever?

I understand the benifits of an I.F, and selectivity. But where does sensitivity come into play. It seems to me the front end is where it matters and not what you do with the signal afterwards.

Why do DC recievers get such a bum rap?

re PA5-HF 5 watt amp.
This is in the 2ND edition of W1FB's QRP Notebook. According to the test, this can be a multiband amp by
band swicthing the harmonic filter. The problem is that the values for R16 and C26 change for each band
as noted on page 131. Is there a optimum value for the components that will be satisfactory for all bands.
Any and all help appreciated.

thanks
Vic

People, I just got an email reply from Bill Kelsey at Kanga (Who supply the kits for all the R2/T2/miniR2/LM2 etc.etc projects * 419-423-4604 *). He has been in contact with Rick KK7B, the designer, and has the following insight for us:

> >In the VFO/TX schematic on pages 42/43 I have noticed a few things:
> >
> >1) I don't see how the CW offset transistor can be an NPN device with
> >its emitter connected to +12V. I reckon they have transposed the
> >emitter and collector terminals. Anyone care to comment?
> >
>
> I think it should be a 2N3906 PNP instead of the 2N3904 (how I would
> have done it). - deletia -

* Correct. The part should be a 2N3906 PNP transistor with its emitter connected to +12V.

>
> >2) The VFO inductor L1 has a tap, but there doesn't appear to be
> >any information on the number of turns up the tap should be. Anyone
> >know what it should be?
>
> Typically, tapping 1/3 the way up usually works. (8 turns) Tap up
> higher if you need more feedback--closer to the ground for less.

* Correct. The tap should be at 6 turns up from ground.

>
> >
> >3) The quadrature generation circuit consisting of L2A/B and
> >associated components gives us no information as to the phasing of
> >the inductor windings.
>
> I'd put the phasing dots next to either of the 100 pF capacitors--but
> not both!--Zack KH6CP/1

* Correct...you know your stuff Zack! One capacitor goes between the wires at one end of the inductor, and the other capacitor between the wires at the other ends of the windings.

There are some other errors/ommisions that I/Bill noticed:

4) Details for L9 in the collector of the 2N3866 o/p tranny were missed off. This should be 29 turns of 28AWG on a T37-2 core.

5) The 390pF capacitor at the collector of the 2N3866 should be 220pF.

Anyone else making one of these?

Assuming you're using a metal mast, and it's clamped to the mast, just ground the mast. #8 copper to an eight foot ground rod. Use approved grounding clamps on both ends. If you're using a non-conducting mast, then place the ground clamp at the bottom of the J in the J-pole and wire to the ground rod as above.

Bob,

You cannot combine two *similar* amplifiers, they have to be essentially
identical. If the signal delay time of both is well matched they can
be combined with broad band transformers. This is done commercially
very often, e.g. in VHF.

Well, it's *easier* to combine two identical amps, but you can combine
similar amps. You just need a line stretcher and a gain leveling pad in
one input leg to make the output phases and amplitudes balance.

No. The radio is inherently a half-duplex design.

A circulator might well cost more than the radio itself. I doubt you can easily make the FX440 run full duplex without adding some separate audio stages, part of the audio is switched between transmit and receive. The selectivity isn't good enough to run good full duplex either. I'd suggest Hamtronics separate transmit and receive modules instead, that's what I use in my homebrew 224.94 MHZ remote base/repeater, very happy with them though they do cost quite a bit more. At 440 MHZ with 5 MHZ separation between transmit and receive you can very easily run separate TX and RX antennas, or used duplexers can be had fairly reasonably priced compared to 146 MHZ units, but you still need good clean transmitters and selective receivers with high dynamic range performance to run full duplex.

>identical. If the signal delay time of both is well matched they can
>be combined with broad band transformers. This is done commercially
>very often, e.g. in VHF.

The combined amplifiers generally have to be as identical as humanly possible. The main problems are gain, phase delay and linearity, and several other less important problems can creep in also.

For example, if gain and phase are matched with external circuitry, a simple thing like diverging gain or phase as supply voltage changes can throw the whole thing out of wack. If the gain or phase varies differently in each amplifier as drive power is changed, the balance will again suffer if the drive power is not held constant.

Another problem occurs if amplifiers are combined AFTER filtering. Filters can shift phase at different rates as frequency, temperature, and/or load impedance change. Combining should never be done after hi-Q or multi-pole filters.

My opinion is "it depends on you and the application". If the requirements are not too tight, the equipment is reasonably close in operating parameters, and you have a good idea of what you're doing, it will work OK. Otherwise, good luck!

I missed Jim's post, but here's a chance to answer his question. The noise generator I got from Advantage seems to have <plenty> of output... I can very easily run it off the top of the screen with a "normal" gain setting on the analyzer (unfortunately, my analyzer doesn't have absolute amplitude calibration, so no accurate output level reading :-( ).

>Someone had mentioned that this technique didn't work with notch

Rick, thanks for that idea. I'll try a bandpass filter as you suggested; I've had no luck seeing notches with any other technique I've tried.

It's not so silly as you might think. At VHF and UHF solid state amplifers are paralled using hybrid combiners with great success. For the HF bands, it is probably more economical to get a bigger tube or to parallel several tubes. (I have carried the tube paralleling to something of an extreme, using 12 planar triodes to get 360 KW pulsed, 1% duty factor at 425 MHz.) The other problem with combining HF amplifiers is tuning them so that the rf has the right phase at each amplifier output to be properly combined. If you have some special reason for wanting to do this, I could suggest how to proceed.

Jim

>analyzer is OK for that much input when you're checking the wideband noise
>without the filter in line).

I would very like like to contruct a noise generator for my spectrum analyzer. However, I have several problems:

1. my spectrum analyzer has a noise floor of about -80dbm. I presume that I can insert a preamp to makeup for a weaker noise source?

2. I can generate noise with with a noise diode, or with a 1N23 diode. I don't understand ENR (Excess Noise Ratio) and how to predict how much power will fall into a given bandwidth. I read the QST artical last year, and I didn't understand it.

3. If I start with a Noise Com NC302 noise diode (ENR is about 30) and amplify it with multiple MAR-3 MMIC devices, how many MMIC devices can I cascade before the +10 dbm compression occurs ? What happens if I exceed the compression point? Also, keep in mind question #1.

4. My spectrum analyzer has an IF of 2050 MHz. Any signal at that frequency overrides all other displayed frequencies. I need a sharp band reject filter! Since I belive that this might be impractical, I'd settle for a low pass filter. It would be nice that it be have a flat response just until about 2 GHz, and then roll off sharply. However, I's again settle for a filter which was flat until 1300 Mhz and then roll off -80 db at 2000 Mhz.

Thanks,
Allen Wallace N7CGH

5274. Re: NE602 sources ?

Believe it or not I just looked at the relatively new DigiKey
web page and found they sell the NE602 for $2.35 or so in
single lot quantities.
Looks like you can order from them online:
http://www.digikey.com/

Look for digikey parts in:
http://www.digikey.com/PartSearch.html

5275. Re: NE602 sources ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-14 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <fa4_9511150230@mba.mba.org>
Source record: 109638

Alan Wong (and his email address wasn't in the post)
added to the thread by asking if there were any replacements
for the NE602.

I guess it depends on what you mean by replacement. Long before
the NE602 came along, there was the MC1496 double-balanced
mixer. It came out about 1970. It was used in the amateur
realm for many years, the only real disadvantage of it was
that it required quite a few external resistors to get it
up and running. ON the other hand, all those resistors meant
that you could adjust things to your liking.

Similar devices came along, made a brief appearance, then
disappeared. Presumably they did exist, but finding where'
to get them in the small quantities needed by the amateur
was the big problem. Texas Instruments had one, and I
seem to recall seeing an Intersil data sheet for something.

Then the NE602 came along, and suddenly it was used everywhere.
Also, it came with the descriptor "gilbert-cell mixer". From
what I've gathered, it is the same type of circuit used in
the venerable MC1496, but the 1496 was never given such a fancy
title.

Of course, one thing in favour of the NE602 is the built in
oscillator. It can be useful in some cases, while I suppose
in others it is a libiality.

The external parts count of the NE602 is much smaller than
the MC1496. On the other hand, I hear that it's dynamic
range is not all that great. Reminds me of a recent thread
in sci.electronics. SOmebody had built an FM BCB receiver
using a 602 in the first mixer, and it was overloading.
Clearly, the device had been chosen because it was what
is being used in all kinds of published circuits. Popular
doesn't always make it the right choice. I've never seen
the data sheet for the NE602, but I do recall reading somewhere
that it had been intended as a second mixer, after some sort
of IF filter, where the need for large dynamic range is not
needed as much.

So finding a device with as few external components as
the 602 might be difficult. Finding one with an internal
oscillator might be difficult too. But if you want a
transistor based double-balanced mixer/modulator using
the "gilbert-cell" configuration, it's bound to show up

in other places.

I recall an article in 73 where the mixer in a Signetics
TDA-7000 (have I got the right number? It's the FM bcb
receiver in an IC) as the product detector in a direct
conversion receiver. The author mentioned that it had
better dynamic range than the 602.

There is the MC1496. You'll have to look up a circuit,
and treat it as a black box replacement for the 602,
but it always used to be a good choice. I am assuming
it's still being made.

Maybe look into those FM receiver IC's intended for
NBFM. They have mixers to drop to the IF frequencies,
I think some have to mixers, and they just might
use the same type of mixer. Check the data sheets.

I've also come across a number of IC's in bcb receivers,
for the front ends. They might be worth looking into
to see if they use suitable mixer circuits. Of course,
where to get them new is another question.

Also, the data sheet for the MC1590, which is a metal-cased
MC1350p IF amplifier, has a circuit for using it as a mixer.
From what I recall it does work out as a double-balanced
mixer, similar to the circuit of the MC1496. The bad part
is that there is amplification after the "mixer" part of the
IC. How much, I don't know since I haven't studied the
circuit much. ON the other hand, it just might be suitalbe
for simple applications.

Hope this is some help.

5276. Re: ** HELP with mic preamp

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-14 00:00:00 UTC
From: Paul Christensen <paulc@jax.se.continental.com>
Message-ID: <48b9il$mgn@usenet.continental.com>
Source record: 109639

What is really needed here is a source follower circuit using the same MPF-102 transistor. I believe this is the circuit as described in the ARRL handbook. The source of the FET should be connected to the +8VDC phantom supply via a 100 Ohm resistor (not 10K as indicated in his earlier posting). Both sides of this resistor are then bypassed to ground with 0.01 MFD capacitors. I prefer metal film types for this, but the garden variety 100VDC disks should be fine.

Now, the drain is connected to ground via a resistor (Rs). The exact value of which is determined by the reciprocal of the FET's transconductance value. This is usually found on the FET's packaging as the "Gm" value. Typical values for Gm are from 3000 to 5500 uS. Therefore, the Rs value will be approximately 180 ohms to 330 ohms. My two FET interfaces use 330 ohms resitors for Rs. The audio is then fed to the transceiver via a coupling capacitor (>10 MFD.) from the junction of the drain and Rs.

It may be necessary to add the R.F. choke you described in series with 100 ohm resistor that connects to the FET's source. Additionally, it doesn't hurt to include one on the input to the FET's gate and at the sudio output.

Of course the microphone element still connects directly to the FET's gate. Some mic preamp circuits show a 100K ohm resistor from the gate to ground. I caution people with D104 or similar crystal-cartridge microphones to use a much higher value. Presently, I am using a 10 megohm resistor for this, and oftentimes it's not needed at all. The crystal element can be thought of as an A.C. generator in series with a capacitor. The capacitance of a typical crystal element may not be much more than 2000 pF - 3000 pF. Even the slightest loading of the FET's input will cause low frequency rolloff.

This combination of crystal element and FET source follower preamp results in an incredibly nice sound for communications audio.

Please see my reply to Gary Coffman. I believe this will answer your questions. The bottom line though is that if you're using the FET as a source-follower (Taking the audio off the FET's drain through a coupling capacitor), then your 10K ohm P.S. current limiting resistor should be in the area of 100 ohms, not 10K ohms. Follow the posting I had written to Gary.

I've built too many of these circuits that work flawlessly and without any stray R.F. problems. In addition to my R.F. choke recommendation, you should also try bonding the interface box with circuit gound.

5281. Small Relays Useful at UHF for 40W Amps

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-15 00:00:00 UTC
From: moyers@cti-pet.com
Message-ID: <moyers.6.0000078A@cti-pet.com>
Source record: 109644

I am looking for an inexpensive, readily available relay (12 V coil) that has been found to be useful in UHF T/R switching applications. I am designing a 40W dual-band (2m/70cm) class C amp for mobile use and need four SPDT relays.

I thought I had struck pay dirt with some miniature relays that Radio Shack sells. Come to find out, upon opening one of these little 10A-rated devices, the commutator is electrically in contact with the "frame". Thus signal is all over the frame and contacts the pole of the magnet. Thus there is considerable cap. to the coil. Ok at 60hz but NOT A GOOD RELAY for VHF or UHF!

Has anyone had experience in this area?

5285. Measuring Filter Group Delay?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-15 00:00:00 UTC
From: john.ackermann@daytonOH.ncr.com
Message-ID: <john.ackermann.414.000A0AA1@daytonOH.ncr.com>
Source record: 109648

I'm working on some radio mods for (sort of) high speed packet and want to characterize the IF channel performance, and particularly what the bandpass response does to data.

Any suggestions on how to measure the group delay of an IF channel? I've heard of a method using a high-deviation modulated FM signal as input, and looking at the output on a spectrum analyzer, but I don't know the details (or whether that would really work).

Thanks...

John Ackermann AG9V

See _Solid State Design For the Radio Amateur_, Fig. 17, p. 26, the "universal QRP transmitter". The book is available from the ARRL and has lots of other schematics and info. There are also several that fit the bill in ARRL's _QRP Classics_.

Go to a *real* roofing supply house for *copper* flashing. Home centers
like Rickel/Channel/Home Depot/etc. generally DO NOT carry copper flashing.

The trick is to find a supplier that will sell it buy the foot. Some will
only want to see you a 100' roll which will cost a small fortune.

One supplier near me sold copper flashing by the foot in 20 and 24 inch widths.
Then I cut the 24" stuff into 3 inch strips for my grounding installation.
It was a bit more work but my net cost for 3 inch copper strap was only
about $0.75/foot.

Copper ain't cheap! :-)

... and make sure you use either stainless steel or brass hardware to
bond all of this copper together.. Do not use galvanized hardware.

I built a NE4040 recently (NN1G now calls it the "SW-1"). I'll check in the instruction manual and see what it says. I imagine it would be an easy trick to move it into the novice band. Let me research it and see what I can find. Also... I know NN1G has an e-mail address. Let me see if I can dig that up also (does anyone have this handy?)

The most straightforward way is to just measure it with a network analyzer.
Most VNA's are quite capable of measuring group delay.

If a network analyzer is unavailable, you must find some other way to
measure phase, as group delay is just -(d[theta]/d[omega]), or minus the
phase slope when plotted with respect to angular frequency.

You could, for example, take a number of data points using a vector
voltmeter. Use the input of the circuit for your phase reference, and then
take data at closely spaced increments throughout the passband. After
you have the data, go back and calculate d[theta]/d[omega] between each
of the points. This is how a network analyzer does the job anyhow. The
instrument measures phase, and software computes the group delay before
plotting.

If your IF is below 13 MHz, you could use an HP3575A phase gain meter in
place of a vector voltmeter. The process is the same.

Have fun,

<snip>
I DONT WANT TO USE THE CURTIS CHIP AND DOESNT NEED TO BE FANCY.
<snip>

Why not the Curtis chip? You can build a very, very tiny keyer using the 8044 chip, and it will work quite well. The power drain of this chip is so small that you don't even need an on/off switch to keep it from draining your batteries! It's also highly RF-resistant if you build the circuit like they suggest. I've included Curtis keyers in a number of homebuilt and kit-built QRP rigs, as well as several HF transceivers (Heath, Ten-Tec, Kenwood TS-430S, etc). I've built them on pieces of 0.1" solder-grid board that were 1" x 1.25". You can't get any smaller than that!

jackwy@clark.net (John Frank) wrote:

> I am looking at using pin diodes to replace the mechanical
>switches in my cable tv switching box.

Why bother with expensive, hard to find PIN diodes? at VHF, 1N914s would work fine, since you aren't transmitting, you can keep them forward biased, and you don't need any carrier lifetime to keep a reversed biased diode on. put 2 or three in series with spreading resistors of 10Meg or so if isolation is a problem..also reverse bias the bejeezus out of them in the off state. Using a "T" configuration is the best bet..2 reverse biased devices in series, with a forward biased shunt to ground in between.

Also take care with layout, you won't have too much trouble getting more stray capacitance than a 12V reverse biased '914s.

PIN diodes are required only at low frequencys (HF), and high signal levels. The large signal cancels the forward bias of the ON devices, and the carrier lifetime must be long enough to ride out a half-cycle of the lowest transmitted frequency. The amount of signal at cable subscriber drop is practically nil, as it simulates what an antenna would pick up in over-the-air TV , so you should easilly be able to keep most any diode forward biased. in this application.

You could adapt any of the schemes used to diode switch, for example, IF filters, to tthis application. The old handbook PIN switch circuit would be okay if you modified it to put "OFF" devices under higher reverse bias, to aid isolation.

BUT: for all the trouble you'd go to...you know a relay works really well! I don't know of anyone running QSK on thier cable system :-)

Buy 2 relays, and tape the second one inside the box, in case the first one ever fails..this will be cheaper than diode switching circuit!

5295. Re:R2D2 a DSP R2

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-15 00:00:00 UTC
From: mack@mails.imed.COM
Message-ID: <9510158164.AA816482551@mails.imed.com>
Source record: 109658

Greetings:

I have not yet worked on an actual circuit, but here is the idea for doing a quadrature in a DSP. I just got the TMS320C26 kit for $99 here at work. One of the applications is a 32 sample FFT algorithm. For those who have done Fourier work, the result is two arrays. One is a cosine and the other is a sine array (real and imaginary). To rotate the original signal by 90 degrees, each cosine term is replaced with the corresponding sine term and the sine term is the negative of the original cosine term. We now have a DFT which is 90 degrees out of phase with the original DFT for all frequencies. To get back to a time domain signal, we do an inverse FFT and voila! we have an in phase and quadrature signal.

The part I haven't had time to simulate is whether a 32 point FFT/inverse FFT will provide a quality phase shift. The idea would be to do the DSP work on samples 1 through 32. The output sample is the first sample of the result. Next we do the DSP work on samples 2 through 33 and output the first sample result. In other words we are always 32 samples back of real time. This has the effect of doing a running average.

Well that is the proposal. Does anyone see any holes in this idea?

One reason is that they demodulate signals and noise on both sides of the
local oscillator frequency. This creates an automatic 3 dB of extra noise
which is detrimental for CW or SSB reception. On weak signals, 3 dB is often
the difference between copying them and not. There are some exotic phasing
techniques which can overcome this, but if you're going to go that far, you
might as well just make a superhet.

I use a D-104 to drive an Icom 751A. It works great, and gets excellent audio reports. I use a single J-310 FET source follower to do the impedance matching. It has nearly nearly identical output voltage and current as the stock hand mic. I think there's a total of five components in the entire circuit! The gate resistor is a 2.2 meg ohm, the source 470 ohm, the supply 9 volts through an automatic turn-off transistor switch (battery saver).

Paul hit the nail on the head, a 100k resistor on the gate is much too low for good response. After a sprinkle of FB-73-801 beads and a few bypass caps I can apply RF directly to the micropone case without RF feedback!

5301. 811A VS 572B Triodes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-15 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <48e56t$qpd@crash.microserve.net>
Source record: 109664

The HF amplifier I use, a Gonset GSB-201, originally came from the factory with (4) 811A tubes. Gonset later made another version of this same amplifier, called the GSB-201 MkII, that used (4) 572B's.

I've been told by one person that the power supply in both versions is the same, which would mean that regardless of the tube, the amplifier was designed with 1,500 V on the plates.

Given the fact that maximum rated plate current is nearly identical for both tube types, changing to 572B's wouldn't appear to have a major impact on the CW/PEP capability of the amplifier. However, the 811A's are limited in terms of full duty cycle power, and that's what I would like to improve. Total rated plate dissipation with the 811A's is 260 watts. Even (3) 572B's would provide 480 watts dissipation, more than sufficient to run 1,000-1,200 watts continuous key down.

The power transformer in this amplifier is at least as large as in the Heath SB-220 I had about fifteen years ago, so I'm reasonably confident the power supply can handle this. The factory input ratings for this amp (with 811A's) were:

1,500 W PEP (SSB), 1,000 W (CW) and 400 W (AM)

Other than the AM rating, there is no mention of full duty cycle power capability. From using the amp however, I know that the 811A's show plate color quickly at 1KW input.

My question is whether anyone knows if the 572B's will be relatively inefficient with 1,500 V on the plates? Marketing being what it is, the fact that Gonset may have used them at this voltage isn't quite sufficient to convince me that the efficiency will be acceptable. The ARRL Handbook shows about 75% efficiency at 1,650 V, but that's in Class C.

The other possibility for adapting to the 572B's would be to remove the filter choke from the power supply and to add additional filter capacitance. My calculations indicate that the change to a capacitor-input supply would provide a plate voltage of approximately 2,350 V. However, other changes would have to be made as well, including new power supply diodes, tank circuit adjustments, and perhaps a larger plate tune capacitor. Further, this would preempt the possibility of using 811A's in the future. I'm very reluctant to make these changes if they're not absolutely necessary in order to use the 572B's. The ability to use either tube type by merely plugging them in is a distinct advantage. Again, I'm looking for improved duty cycle, not

additional peak power.

Any comments will be appreciated. I'd especially like to hear from anyone who owns or has used the MKII version of this amplifier.

73,

Jack WB3U

5302. Re: Spec Analyzer + Noise Gen = Tracking Generator?

Newsgroup: rec.radio.amateur.homebrew

Source record: 109665

Richard Karlquist (rkarlqu@scd.hp.com) wrote:

: Someone had mentioned that this technique didn't work with notch
: filters. The reason it doesn't is that the wideband noise overloads
: the mixer in the spectrum analyzer and fills in the notch. If your
: spectrum analyzer has a really good dynamic range, you might be
: able to adjust the attenuator just right and get away with it, if you
: don't need to see down more than 40 dB or so. Otherwise, use a wider
: bandpass filter as a "roughing" filter in cascade with the notch filter
: to avoid overload.

Yes, you get bitten badly in the dynamic range department when trying
to use broadband noise as a stimulus.

The bandwidth of your noise source, or thing under test (whichever is narrower) sets the total power hitting the first mixer of the analyser. This, as Rick says, is why notch filters are a problem. All you can do is crank in some front-end attenuation. To see the shape of your filter under test, you have to use a narrow enough IF filter setting to be able to resolve the skirt of the filter under test (and this is usually worse still for notch filters...) The net result is that your analyser has to be set up in a way that is very unfavourable for percieved noise floor, so you don't get to see very far down the slope of your filter before you hit analyser limitations. Take some of the RF attenuation out and you get mixer overload spreading noise around, filling up the stop band again.

The EMC tests in Europe require spectrum analysers to be able to correctly measure a test signal designed to resemble the broadband stuff from an arcing contact. The standard test source is a capacitor discharged by a vibrating relay contact, the PRF is about 1 kHz, the noise is a 1kHz comb pretty flat to 1 GHz and the pulse amplitude can be adjusted up to several tens of volts. Think of connecting a mini spark transmitter to your pride and joy receiver... The result is a devilish specification that is properly justified by real-world interference measurements, but forces the use of a tracking preselector in order for the necessary measurement dynamic range to be met with 120kHz and 9 kHz resolution bandwidths. This is simply the same problem...

Cheers
David GM4ZNX

5303. Looking for advice: Small Relays Useful at UHF for 40W Amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-15 00:00:00 UTC
From: moyers@cti-pet.com
Message-ID: <moyers.7.001755FB@cti-pet.com>
Source record: 109666

I am looking for an inexpensive, readily available relay (12 V coil) that has been found to be useful in UHF T/R switching applications. I am designing a 40W dual-band (2m/70cm) class C amp for mobile use and need four SPDT relays.

I thought I had struck pay dirt with some miniature relays that Radio Shack sells. Come to find out, upon opening one of these little 10A-rated devices, the commutator is electrically in contact with the "frame". Thus signal is all over the frame and contacts the pole of the magnet. Thus there is considerable cap. to the coil. Ok at 60hz but NOT A GOOD RELAY for VHF or UHF!

Has anyone had experience in this area?

>Flashing available at any home improvement store"

What you want is roofing flashing. It comes in a 5 inch width on long
rolls. You really don't want to use aluminum, however. You want copper
flashing. Aluminum is too difficult to make good electrical connections,
that pesky insulating oxide coating you know.

>The sheets look interesting, since that would seem to provide a large
>surface area to use to tie the individual pieces of equipment to. It
>could be pleaced under the rigs, or on the back side of the rig tabel,
>but I don't know if that is the "best way".

It isn't. You want all your equipment grounding conductors to tie
to a *single point*.

>If you are familiar with "flashing" and or have any suggestions on the
>best way to ground the equipment, I would appreciate your comments. I
>live in any environment where I have to be extremely sensitive the RFI /
>EMI and I want to make sure I do everything on my part.

Don't look to grounding to cure RFI/EMi problems. That's just a bandaid
that attempts to suppress a symptom (and often makes it worse not better).
What you want to do in such cases is to solve the source of the problem,
not just try to treat the symptom.

>Watkins-Johnson receiver, or the boxes Rohde described in his articles.

Well, 12 bits will sort of work, giving you a dynamic range of about
85 db. But you really want more bits. 16 works well if you use AGC,
and 32 bits gives you 160 db, which is more than enough without AGC.
You can use the DSP to generate an AGC signal when the ADC approaches
its limit. Used artfully, even the 45 db range of an 8 bit system
can be useable if the receiver offers single signal capability.

Of course the R2 requires the audio quadrature to achieve single
signal capability, so that means your DSP has to have sufficient
dynamic range to deal with a strong signal on the image channel.
Hence, I'd recomend a minimum sample size of 16 bits. I have used
the Analog Devices kit with the R2. It uses a 16 bit CODEC.

Gary

I have a 1DP1 tube and would like to get information on the pin out
and filiment requirements for this tube. Any one have any info?

Thanks, Jim, WA6SDM

There is a related 3-part article to this posting, entitled VLF STORY.
originally posted to rec.radio.shortwave 59300-59302.

(Re-post note: By this time, those probably have
been archived and are no longer available on the rec.radio.shortwave
USENET group for reading. If you want the 3-part article reposted,
please e-mail me. I will re-post the article if enough folks request
it!
Also, note the WWW URL toward the end of this posting for WAV file
availibility. I noticed I misspelled the WWW URL, so here it is--
correct at last: http://www-pw.physics.uiowa.edu/mcgreevy/
This URL will be repeated at the end of this posting.

Use a fixed-width font such as courier 10cpi or "line Printer"
if viewing in graphical editor/word-processor,
or use Windows Notepad or a DOS text editor such as edit.com.

Thanks to everyone's nice comments! Due to many requests, here is
the schematic to the McGreevy BBB-4 ELF/VLF "whistler" receiver:

REVISED 20 AUG 1995, WITH LINE-NUMBERS INSERTED IN SCHEMATIC AREA
AND ALSO DUE TO A PART BEING LEFT OUT!
==========
S. P. McGreevy BBB-4 Naturally-Occurring V.L.F. Phenomena E-field
Receiver ("Whistler Receiver") For Broadband 0.2 to 11 kHz Reception
of naturally-occurring radio phenomena.

(Originally copyright 1993 S. P. McGreevy). spmcgrvy@ix.netcom.com

Snail: 45 Elda Drive, San Rafael, CA 94903-3723, U.S.A.

REVISED ASCII SCHEMATIC OF McGREEVY BBB-4 ELF/VLF RECEIVER w/LINE #'S:
(Sorry about the yucky ascii text "graphics" -- I'm not too good
at doing schematics using text characters, but I wanted this to
be fully compatible with the text-only nature of USENET, etc.

NOTE: I've added line numbers to aid with "fixing" any scrambled lines:
These numbers are at the BEGINNING of each line in schematic (01 to
72).

The "BBB-4" is a broadband 0.2 to 11 kHz V.L.F. receiver with a passband peak at approximately 2 kHz, and is designed to receive naturally-occurring V.L.F. phenomena (such as "whistlers") that occur as electromagnetic (radio) waves at audio-frequencies. This receiver was designed to be hand-held, and its output patched to a microphone-level input such as a tape-recorder or speaker-amplifier (such as the one available at Radio Shack ("Mini Audio Amplifier/Speaker" cat. # 277-1008).

Dissatisfied with more complicated and cumbersome multi-turn loop receiver schemes, I opted to design a whistler receiver which was simple to build and use, but was as sensitive and low-noise as possible while being highly-immune to broadcast station overload.

The BBB-4 V.L.F. receiver circuit ("BBB-4" standing for a fourth version of my "Bare-Bones-Basic" designs) is remarkably sensitive and works very well with short whip antennas between 30-60 inches in length,
since it operates on the same principle as high-impedance "active antennas"
designed for other frequency ranges (such as long, medium or shortwaves).
The BBB-4, due to its F.E.T. "front-end" being a high-performance J-FET,
has an input impedance of about 10 megohms, which is why the short whip

antenna--more correctly called an "electrical-field probe"--works fantastically
for being such a tiny fraction of the received-frequencies' wavelengths in
size (the ultimate isotropic antenna).

R1 and C2 act as a roll-off to frequencies above about 20 kHz, efficiently eliminating potential receiver overload/intermod from Loran-C
(100 kHz), strong AM-BCB signals or SWBC signals, and frequencies up into the VHF ranges. R2 sets the gate impedance for the J-FET. R4 and R3
set the optimum bias on the FET for maximum dynamic range and minimum susceptibility to overload and intermod. C3 and C6 slightly helps roll-off
low-frequencies such as powerline "hum." The "pi-filter" consisting of C4,
L1 and C5 roll-off frequencies beginning at about 7 kHz, so there are not
excessive levels of 10.2 - 13.6 kHz "Omega" signals or higher frequency
signals, which can create problems with the recording system connected to
the output of the receiver. R5 to R8 , Q2 and C7 form a fairly low-noise
Class-A audio amplifier which boosts the output from Q1 to a level plenty for
all microphone-level recorder inputs and even some more "sensitive" line-
level inputs. Bypassing R3 (1K) with a 2.2 uF cap will boost FET gain somewhat, esp. the higher frequencies--depending on your location and listening conditions, this may or may not be desireable.

The circuit can be built on perfboard such as IC-LSI boards or even wired point-to-point, as layout is not very critical. However, the parts'
values ARE critical for optimum passband shape and sensitivity. L1, the
inductor, can either be a 160-200 mH choke or the Radio-Shack 1K to 8 ohm audio

transformer available at Radio-Shack (cat. # 273-1380). Use the black and
green or black and blue wires (the center-tap and one end of the primary
winding). The audio transformer was used since it is easily available at
Radio Shack stores. In fact, ALL the parts with the exception of the 2N5484
FET are available at Radio Shack. Very good performance (but slightly
reduced gain) can also be had if a 2N3819 J-FET, available at Radio Shack,
is used. If so, R3 must be 220 ohm and R4 must be 1K, because the 2N3819
needs different biasing than the 2N5484. Also, if you use the Radio Shack
2N3819 FET, you might wish to reduce C4 and C5 to .033 mF, since there
will be less high audio-frequency output from the 2N3819. Keep C4 and C5
047 mF if you live in Hawaii or within 300 miles of La Moure, ND (south-
eastern North Dakota) due to the Omega-navigation transmitters (frequency
stepping from 10.2 to 13.6 kHz) being located there. Capacitors C4 and C5
work with L1 to reduce Omega to tolerable levels. Solder the J-FET into the
circuit LAST, and take measures to protect the FET from static electricity.

The total cost for parts (not including an enclosure) for the BBB-4 are in the
neighborhood of $15-20 U.S. A rugged telescoping-whip antenna is the GROVE
ENTERPRISES "ANT-8" 7-46-inch telescoping whip with a BNC
connector. This is available for $16.95 from Grove Enterprises, P.O. Box 98,
Brasstown, NC 28902-0098, U.S.A. (Order Line 1 (800) 438-8155. They
send out a free catalog.

Another telescoping whip antenna of like design is
available from C. CRANE RADIO CO. in Fortuna, CA in Fortuna,
California (800) 522-TUNE (522-8863). E-field-probe receivers of this type
need to be operated at locations away from trees, buildings, or other
obstacles by about 100 feet/30 meters. This is because received
signal levels (due to E-field attenuation) will be poor if the receiver is
operated too near (or under) such obstructions.

The greatest nemesis to monitoring and recording naturally occurring
VLF phenomena are electric a.c. powerlines, which emit annoying hum at

50/60 Hertz and also harmonics beyond 3 kHz. The only cure for this "hum"
problem it to locate monitoring sites well away from a.c. powerlines. Locations at least 1/2 mile/1 km or so away from a.c. powerlines will begin
to be acceptable, though the farther you can get from powerlines, the better.

Hilly or mountainous terrain (with open areas free of trees) offer larger areas
away from powerlines, though large fields and meadows where the powerlines are shielded by trees, etc. may be surprisingly hum-free. Remote
locations such as deep into desert and wilderness regions offer the most
rewarding locations, both aesthetically and electrically, to listen, and you may
be able to get over 10 miles from the nearest powerline. If so, you can make
the receiver's antenna several meters in length (keeping it vertical) for
maximum sensitivity. Longer vertical antennas or horizontal wires may either overload the receiver, or in the case of long/low wires, will create a
mismatch which will actually reduce output. Experiment here.

NOTE: A 100 mH choke across C5 (th secone .47 cap in the audio filter will greatly reduce the below 1 kHz frequencies, including pesky power-line hum. This may enable you to listen far closer to AC power-lines including even some backyard locations!

Grounding is non-critical. High-impedance FET receivers of this type need only minimal grounding to work well_even just the body of the listener
holding the metal enclosure of the receiver will be adequate in most cases. If
recording, it is best to stick a 8-10 inch ground rod into the soil to reduce the
possibility of feedback with some tape recorders. Also, a small ground-rod
(8-10 inches long) will cut noise from body or foot movements (due to capacitive interaction with the ground). If you ground the receiver to objects
such as fences, beware that certain grounds may couple a.c. powerline noise
to the receiver, which is why I recommend a simple Earth ground.

Better quality tape recorders, with adjustable input level controls, are
desirable, as "cheapie" portable recorders with auto-level control will often

have annoying variations in record level due to lightning-sferics. And, these
cheap recorders also put noise of their own onto the tape. A shielded 600 ohm
patch-cord will suffice between the output of the BBB-4 and microphone
input of a tape recorder.

The most common naturally occurring V.L.F. emissions to be heard
are the myriad "crackling and popping" sounds of lightning-stroke
electromagnetic impulses from lightning storms within a couple thousand-
mile radius of the listener. Since there are nearly 100 lightning storms in
progress anywhere on the Earth at any given time, and that millions of
lightning strokes happen daily, there is never a moment when these lightning
"sferics" will not be heard. However, the density and strength of lightning
sferics can vary day-to-day and hour-to-hour. Mid-winter offers the lowest
density of sferics, and summer evenings can be full of a dense barrage of
strong sferics.

The other most common (and most awesome) sounds are "whistlers"_eerie
descending tones caused when the lightning electromagnetic energy gets
"ducted" along Earth's magnetic lines-of-force (magnetosphere) to the
opposite polar hemisphere, then gets rebounded back to the vicinity of the
originating lightning stroke impulse. However, there doesn't have to be
lightning within sight or even a few hundred miles of your listening
location_lightning from storms up to thousands of miles away, particularly if
more to the north of your location, can generate large whistlers which are
heard continent-wide. On the other hand, it's quite spectacular to watch
distant lightning storms generate whistlers in the receiver's output_you hear
the huge "crack" of the lightning impulse sferic, then, if the conditions to
support whistlers are occurring, a whistler may follow from 1 to 2 seconds
after the lightning stroke.

Optimum times to listen for natural V.L.F. phenomena, such as
whistlers, are between sunset and sunrise, with the midnight to sunrise period
generally being the best. Statistically, the greatest activity to be heard is

around dawn and sunrise (4-7 a.m. local time)_sferics tend to be fairly low as
compared to the sunset period.

Dawn Chorus can occur during magnetic-
storms, and will peak anywhere from an hour before sunrise to 2 hours past
sunrise. Whistlers can occur at anytime, but the period of minimum
frequency is midday. Sometimes, activity can also occur just after sunset,
but sferics will be fiercer. Lightning sferics will be most fierce during
summer afternoons and minimum (generally) an hour or so after sunrise until
thunderstorm activity picks up later on. Winter can present delightfully low
lightning sferics_other activity will be more "in the clear."

Tweeks, the "ringing/pinging" sounds of sferics caused by the Earth-
surface/ionosphere "waveguide," will be best from an hour after sunset to 2-3
a.m. local time, gradually tapering off toward sunrise. Their number and
intensity of "pinginess" can vary from night to night_some nights they can
sound rather "pale," but other nights they can ring in a variety of beautiful
mixtures and pitches. Whistlers, which may or may not be heard on some

days or even weeks, can range in sound from quite pure notes to very diffuse
"breathy" sounds. They can swoop in frequency from very high to low, or
abruptly cut-off as they descend in pitch.

Don't be discouraged if you listen for several hours, or several sessions on
different days, without hearing whistlers or other natural radio phenomena.
When you DO hear them, it will make up for the "dry" times, as there is

nothing like "live" listening!

Listeners located north between 40-55 degrees north or south latitude
are in the optimum latitudes for monitoring natural V.L.F. phenomena. If
you can see visible Aurora (Northern/Southern Lights) from your location,
you are at a great location for natural V.L.F phenomena monitoring!
Latitudes between 20-30 degrees north and south will hear less, but at times,
still loud phenomena. I've heard whistlers just fine in

Hawaii_presumably
those whistlers were louder farther north, but still, they were heard!

DO NOT operate this receiver (or any other) when nearby lightning
threatens! Take appropriate lightning precautions when lightning is
occurring nearby (within 5-10 miles). Nearby lightning will cause
excessively loud sferics in the receiver's output, and whistlers will
not be
louder just because lightning is close-by. Reserve listening for fair
weather
periods_most often, the best and loudest natural V.L.F. phenomena will
happen during clear weather, since lightning can be quite distant, as
mentioned above, and still spawn loud whistlers.

If you would like to purchase a ready-made receiver which is
fashioned like a "Walkman-style" whistler receiver, e-mail me for
details. I don't want to "advertise" here.

The Longwave Club of America also has other designs of ELF/VLF
"whistler"
receivers, and has a BBS run by member John Davis. The LWCA BBS is at
(706) 672-0360 with speeds up to 9600 (8,N,1). Download the
ALLFILES.TXT or ALLFILES.ZIP for listing of files avail on this BBS.

A WWW URL of natural radio WAV files (most 8 bit/11 kHz sampling
compatible with Windows "speaker.drv" as well as 8-bit sound cards,
plus a
few 16-bit files for 16-bit sound cards are available for downloading
at:

http://www-pw.physics.uiowa.edu/mcgreevy/

Special thanks to Larry Granroth a the U. of Iowa for doing this for
me!

Coordinated monitoring of naturally occurring V.L.F. phenomena
among individuals and groups has a strong potential to uncover new and
previously unknown characteristics of these phenomena, particularly if
those
monitoring simultaneously are located hundreds and thousands of miles
apart. Research and understanding of V.L.F. phenomena has been
hindered
by a lack of listeners, which is something a few research groups, both
amateur and professional, are attempting to alleviate.

I hope you enjoy this rcvr. and are interested in monitoring and
studying naturally occurring VLF radio phenomena for yourself. It is
quite
fascinating, especially when one ponders the fact that Earth's natural
radio
emissions have been "sounding-off" way before we Humans came into
existence and started making radio waves of our own! Happy Listening!

Stephen P. McGreevy
Originally released November 1993, updated November 1995

Additional Tips:

1) A 100-200 mH inductor connected across C5 the will act as a high-pass filter, nicely attenuating 60-360 Hz powerline emissions (hum).

2) If you want less gain from the Q2 stage (and slightly lower noise), reduce R8
to 4.7K.

3) Listen to WWV-shortwave (2.5, 5, 10, 15, 20 MHz) for geo-magnetic indices at 18 min. past each hour (WWVH-Hawaii at :45). A K-index at or above 3 indicates enhanced conditions for natural phenomena,
especially chorus.

The formula for the equivalent resistance of two parallel resistors
is their product divided by their sum.

Sorry, I work mostly with spreadsheets so I don't have a Basic formula
for determining one resistor based on the other resistor and the
equivalent resistance.

In the example you cited, placing a 1,000 ohm resistor in parallel
with the 100 ohm yields 90.9 ohms.

A new tribander is out from Standard: the 568A. It receives a surprising array of frequencies, including 800-1300MHz. Does anyone know of mods for recovering the interesting parts of the 800 realm? I've checked Oakland and can't get through to AD4HL's BBS (at 615-537-6051).

Does anyone have one of these radios? What do you think?

I'd also like to get a general feeling for what people think about the Standard brand.

In the market,
Mike

I understand that Jon Bloom (the editor) and his wife both work for ARRL in publications. They had a baby this summer (their first) and this has interrupted the schedule for QEX.

I received my September issue Monday.

Honest, Jon and his crew (if there is anyone besides him) are working furiously to get the magazine back on schedule. Jon tells me that we will get ALL of the issues, albeit a little late. I talked to Zack Lau at Microwave update, so I know that articles for each of the issues are to Jon. All Jon needs to do is get the magazines edited and put together.

My request to y'all is to give Jon until the first of the year at least before you get too upset.

I thank you and I'm sure Jon appreciates any understanding on this.

>
>Which Analog Devices kit did you use? The EZKIT Lite?

Yes.

>How did you interface the I and Q outputs of the R2 to the A/D?

The I and Q outputs are available at the emitters of Q3 and Q6.
Some sort of gain rider is helpful to stay in the center of the
CODEC's range. I used a stereo Volumax I happened to have laying
around, but there are single chip solutions too which can be
driven by a fed back signal from the DSP if you want to experiment
with adaptive AGC.

>And finally, what did you use in the Analog Devices to achieve the 90
>degree phase shift? An allpass filter, a Hilbert Transform?

Right, a Hilbert transform gives you the required 90 degree phase
shift to generate the single signal output. You can then implement
any filters you may wish to apply to the resulting signal. Or, you
can use the quadrature inputs directly to a DSP QPSK demodulator for
data.

From: Jim Devenport <jdevenport@lanl.gov>
Message-ID: <48frbu$mlv@newshost.lanl.gov>
Source record: 109539

I've had good luck using surplus SPDT magnetic reed relays with
a coaxial sleeve of RG58 shield braid surrounding it and a
homebrew solenoid coil wound around the outside. I never used
it at 440 but did use them extensively at 146 MHZ in amps and
transverters for the VHF RF switching. Never looked at them
with more than a Bird for loss/SWR data but they certainly
worked much better than frame relays!
Motorola makes a commercial version of these relays used in the
Micor/Mocom 70 transceivers and USED to retail for around 20
bucks apiece. You might enquire at your nearby 2-way repair
shops, especially Motorola shops, if they have bad relays they
can give you they can be fixed easily by replacing the bad
internal reed switch (there are 2 inside) with a spst reed
robbable from the small Radio Shack reed relays. A single
rivet holds the relay housing together which is easily
defeated. These relays are used throught the 470 MHZ range in
Motorolas.

5325. QST Tech Errors.... Common?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-16 00:00:00 UTC
From: pete brunelli <pcb@connix.com>
Message-ID: <48fvua$1i4@comet.connix.com>
Source record: 109540

I know that it is prudent to wait an issue or two before diving into
a homebrew design from QST, but the November issue was chock full.
The 20M QRP rig appears to have been a forest of errors and omissions
and the broadband transmitting wire article was pathetic considering the
lack of complexity.

This is not as much flame-bait as an observation by a ham who is trying
to justify renewing my league membership which has lapsed for about a year.
Maybe the additional support will equal better tech editing, but since the
tech editor was "behind the diamond" in the same issue, i doubt it.

I have a few older sweep/signal generators for sale, but they are pretty big, and shipping them is not an option for me. I am located in Central CT and would consider a short drive to meet a prospective buyer.

2 - Alfred Model 650 Sweep Oscillator
1 model 652 1.7-4.2 gig module
2 model 654 7.0-12.4 gig modules
1 model 657 10-15.5 gig module
1 model 653 3.7-8.3 gig module
1 model 659 26.5-40 gig module.

This gear is in good physical shape, but is as-is. If nothing else, it is a veritable treasure chest of parts. The modules have watkins-johnson reverse wave oscillators and either N connectors or waveguides. The modules are complete with tuning scales for the master unit.

Offers?

Hi there Tom, you seem very sceptical but.....

For a couple of years I ran two Palomar 350 amps into a vertical.
If you aren't familiar with these amps they use 2 6LF6 tubes driving 4
6LF6 tubes.
Yes I worked 11 and 10 meters with them. I had no problem whatsoever with
the splitter-combiner that I made for the system. The only reason I don't
run them still is because of the price of new tubes. I still use the power
combiner but in reverse as a power divider (splitter) to feed those two
stacked Moonraker 4's from a single Palomar 350.

Yeah. I know two means 3db. Undetectable to the human ear. Barely
discernable
on a visual indicator,... and all that.

From that experience I went on to develop a Power combiner for sale to
others
that might need something like that.

One user of the PC1500 used two different amps on his system. (I hear one
of them ."You can't do that!" warnings from the second row.) A transistor
and a tube amp. Each with about the same output. He said everything was
allright. I haven't heard from him since so I suppose the PC1500 is still
going.

I am glad that I was able to accomplish this and many other downright (You
can't do that!) dirty tricks in this amazing realm of RF.

Hi Barry,

You might consider the Wilderness Radio KC1. This is a keyer AND frequency counter on a single small board (0.8" x 2.5"). You can build it into anything; only draws 4mA.

The keyer has two iambic modes and 50 characters of nonvolatile message buffering. All parameters are entered using the keyer paddle, e.g. weight, QSK delay, messages, etc.

The frequency counter does not use a display. Instead it reports your operating frequency as three digits in Morse code (to 1kHz), by sending audio tones directly to the rig's audio amplifier stage. You use the keyer paddle to program an offset, so it will work with rigs having any mixing scheme. It's especially nice for rigs that don't have a calibrated VFO dial.

The KC1 is $44.50 as a full kit with PC board, controls, and all parts, including a programmed 18-pin microprocessor that does most of the work. I designed the unit for Wilderness Radio, so if you have any technical questions let me know.

Wilderness Radio can be contacted at 415-494-3806. Talk to Bob Dyer, KD6VIO.

>Those airline headphones have a impedance of around 400 OHms per
earpiece.
Connecting them in series will give U 800 Ohm. That might be close
enough for U.

>Or you can use the telephone earpieces from old telephones.

When you say "old", do you mean old as in "discarded", or old as in
"antique"? I was under the impression that impedance for contemporary
standard earpieces was something like 75-100 ohms. I didnt see the earlier
posts, so I presume the original question had to do with high impedance
headphones for, say, a crystal radio or the like.

In that case, using a 8ohm to 1kohm audio transformer in conjuction with
some modern 8 ohm headphones might do the trick. Or, maybe the original
poster should be advised to cobble together a little amp out of a 8 pin
amp chip (Im thinking the LM386), and again use modern headphones or a
little speaker.

>
>
>Even a small program written in basic would be help.

Rx=-Rf*Ri/(Rf-Ri)

Where Rx is the resistor value you need to put in parallel
with Ri, your initial value, and Rf is the final desired
resistance. So for your example:

Rx=-91k*100k/(91k-100k)=1.011M

So you need a 1.011 megohm resistor in parallel with the 100k
to give you your 91k final resistance. Just enter the above
formula into a Mathcad worksheet and you'll always have it.

Well, you've got to have switchable LC networks for a multi-band
amp anyway, so you might as well design them to include the desired
phase shift. Or were you thinking about just using broad band amps
and putting up with the spurious and harmonic output?

The ENR of a noise source is the amount of noise it outputs in excess of the normal amount you would see from a matched termination. A good rule of thumb is at 290 degrees K (17 C or a little lower than room temp) the noise level from a resistive termination would be -174dBm/Hz. I other words if you had a perfect spectrum analyzer with a 1Hz bandwidth you would see a noise floor of -174dBm with the input terminated. A 30 ENR source would give you -144dBm/Hz. If your bandwidth is 1 MHz then the noise energy is (10 log 1E6) + Noise level at 1Hz BW. With your 30 ENR source the noise level would be 60dBHz + -144dBm/Hz = -84dBm. Amplifing the noise source is not a problem, just give yourself about 20dB of head room on compression to keep things linear.

The manual for the FX-440 doesn't instruct you to wind any coils;
small 15nH pre-wound coils are used throughout the front end.

>I haven't looked at a recent one of these kits, but early on the

The FX-440 implements a lock detect to disable the transmitter under
conditions of unlock.

5342. SAW filer

Does anyone know a manufactor or source for an SAW filter with a single pass-band of about 800 Khz (-3dB). There is no strict centerfreqency needed, but somewhere between 24 MHz and 48 MHz would be great (36 MHz preferably).

We know of a MMIC vendor who admitted that their claims of
"unconditionally stable" were based on computer simulations,
not real tests. Certainly, parasitic ground lead inductance
in the actual application is very critical both w.r.t. stability
and frequency response. It's not really a problem with the
term "unconditionally stable" being a misnomer, it's just
specsmanship as usual--like rating power transistors at "100
watts, at 25 degrees C baseplate temperature" (i.e. an infinite
heat sink of infinite thermal conductivity).

I received a call today from a ham who would not identify himself. I repeatedly asked him who he was, even saying to him that if he had an opinion worth anything it is reasonable to expect he state who he was. Still he he refused. I then commented that he was "so typical ham, no guts." My wife then told me to get off the phone and stop wasting time with gutless hams who hide behind their mikes. As I made one more effort to identify the caller, he hung up. He also made a veiled threat that bad things would happen to me, I retorted I might take it more seriously if he were not a gutless ham.

This call is just so typical of hams, brave at a distance.

I am looking at a couple things that would use WWV time service. I need to know about variations in prop delay over a short distance and moderate time periods. If two stations are separated by 300 miles or so what amount will the prop delay change relative to each other? This change is other than the delay due to the differences in distance from the transmiter which can be modeled as a constant. In other words, if the signal is used to drive clockx that have a constant compensation for the prop delay due to distance what is the worst time difference in the two clocks?

Does your modem support half duplex Bell 202 signaling? If so, it
can be used for the modem section of your TNC. For the PAD function,
you'll still need to do some building and programming.

Note: most modems made after 1977 do *not* support Bell 202, and
most "smart" modems won't get out of your way and insist on doing
connections the "telco way" instead of the "radio way". In short,
any use you'd find for your telco modem on packet would be mainly
for the salvaged case and power supply.

I beleive what you are describing is one method of performing a Hilbert transform. This is a pretty standard thing, and I'd bet you could come up with some example code for the 'C2x family from the TI BBS/web site. The 90-degree phase shift in the Hilbert transform is perfect, and thus this is a great way to make the baseband inputs to an I/Q signal generator -- i.e. for SSB or whatever.

I use isopropyl alcohol, which is a safe and reasonably effective solvant that leaves no residue. Buy the 99+% anhydrous version (which you can get at a drug store for about $2.00), and not the 70% rubbing alcohol version. Isopropyl alcohol also makes a good flux remover -- not as good as trichlor or some of the other solvants -- but you'll live longer to enjoy your rig.

>
>73, Moritz DL5UH

Moritz is correct!!!!!!!!!!!!! But let me again add that you can NOT combine two HF amplifiers with hi-Q input and output networks with ANY type of practical system. The phase shift varies wildly with tuning, loading, and input circuit adjustments. It will vary with temperature, the gain will vary with drive level, etc.

It is absolutely not a good idea!

Isopropyl alcohol will leave a residue, Ampex forbids its use for cleaning
video heads for that reason. Toluene is recomended, though of course it
attacks plastics, and the EPA hates it, or Freon TF can be used, but the
EPA hates that too. Methanol is somewhat better than isopropyl for not
leaving a residue, and its use may be tolerable, though meth is toxic
and should only be used in a well ventilated area (you could go blind).
Freon TF is the only really safe and effective solvent, but our benighted
leaders think the sky is falling and are making it harder and harder to get.

Many, many years ago someone told me that Tektronix cleaned scopes sent
back for repair by dumping the whole thing into a bath of hot water with
a detergent. I think all the circuitry was built onto ceramic tag strips
then and the switches were ceramic. They probably took out all the
valves, CRT, etc.

>Speaking of HAM radios, could this group help me out? Every time I go and
>dive with my radio set, the fuse blows. What's the trick here?
>

Ah, yes...
There was a time when having a HAM ticket *meant* something...
When a fuse blows consistantly, it's because there's more current going thru the fuse than the fuse is rated to carry. The fuse, being a safety device, blows to prevent this excess current from flowing, possibly damaging something.
Check to make sure the fuse is the proper rating for the gear. Do *not* replace it with a higher-rated fuse! If it is the correct fuse, then the gear is drawing too much current. This needs to be corrected. Maybe it's a short in the power line, maybe the gear is not a boat anchor. Either extreme, and all points in between should be checked, and corrected.
Good luck.
Bill

Hi Wayne
I'm new to internet but use Mini-Circuits for block gain at wwvb freq to
get
accurate 60khz into shack from voltage probe out in the woods with
simple tunes 'j' fet.
Also strip 3.579545 from color burst oscillator on network sync.
Am looking for best multiplier/divider loop to get 'standard' freqs from
this
very accurate source.
Also using the 9960 chain of the Nantucket Loran 'C' which when multiplied
249 times is 2.5mhz with .000256 ppm 'wow'
Am looking to phase lock my 10ghz brick to within about 3hz...
Hope this got there, de daveaa1a@aol.com

What a poet -- and exactly how I feel with my R2. My feeling when I
first turned it on on 40 meters at 2 am after finishing it was "surfing
the ether", and I still feel that way every time I turn it on.

5367. Frequency Calibration, Frequency Netting, 3.58 Mhz and Loran 'C'

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-18 00:00:00 UTC
From: daveaa1a@aol.com
Message-ID: <48l7an$45l@newsbf02.news.aol.com>
Source record: 109482

Can anyone steer me towards articles using 3.579545 color burst off network
or using Loran 'C' pulses to use as frequency standard and also
multiplyers and programmable dividers to come up with 100khz 1 mhz etc.

I am current stripping Newtork Burst at 3.579545 and find some are better
than others. Also Loran 'C' from here is Chain #9960 which comes out to a
freq. near 10 khz and multiplies 249 times to 2.5 mhz with precesion to 3
hertz at 10ghz.
I get .000256ppm. Will be ultra phase locking my 10ghz brick so as to
make way
for spread spectrum and sync-lock. So far so good. will like to swap
stories
with like minded folks.

Thanks for any help.

Hello,
Anybody out there building laser comms? I'm using 632/680/780 nm for voice, video, data.
Another friend and I have tried a twelve mile path and ended up with many excess db's, like 40 or so. It's cheap, fun, and interesting.
Am using the PIN photo diodes and a killer low noise amp and transmitting on 20 dollar small diodes 5 milliwatt. This stuff is like my first run in with a crystal set 50 years ago.

Hi
I just got off a tanker on the west coast which i work on and copied wwvb
20 db over noise on the console receiver at 60khz.
It gets to new england weaker here if i use a voltage probe antenna narrow
band and out in the 'quiet' woods.
Now i'm stripping off 3.579545 from cable t.v. network sync and getting
some good 10-9th numbers.
Also stripping loran 'C' from Nantucket comes out at 9960 plus the zero
for the time in microseconds then into 1 gives a signal just over 10khz
when multiplied
by 249 gives 2.5mhz at .000256 ppm 'wow'
Depending accuracy of loran can see 3 hertz error in my 10ghz transverter.
Can steer you to some good tips towards 'quiet' l.f. antenna and scoop
that
45 degree phase shifted 60 khz carrier from boulder, co. It should be very
useful.
I want to spread spectrum and to c.c.w./data
Soon we will all be 'Gen-Locked' for 29 bux at Radio Shack unit maybe??.
Tnx and 73's from DAVEAA1A@AOL.COM

Wayne
I did use these MINI-CIRCUIT bnlock gain and tuned ckts for
T.R.F. receiver hook up for vlf WWVB
Also use J-FET preamp out in the 'quiet' woods for receiving.
Havnt made end of TRF run digital stuff yet tho.

It's worth doing I'm sure.

Hi
Why not pur a 68K and a 22K in series. 90K should work.
You might even get closer by testing the value of several.

As simple as that.

>ashworth@hevanet.com

Hi Dennis,

Since I deal with high power RF design and service all day, I thought I'd throw my 2 cents in.

I wouldn't do more than blow the switch out with freon or high pressure air. The tarnish doesn't hurt a thing, leave it alone!!!! It's probably silver oxide, and will wipe away by contact pressure at the contact point all on it's own. It looks worse than it really is.

If the switch is coated with tar or goo from smoking, I'd use alcaholanhydrous alcohol.

Remember if you leave ANY conductive film on the ceramic, you can destroy the switch. This situation has unique requirements. I wouldn't soak it in ANYTHING that might dry and leave a goo, even nice things like Root Beer or Kool-aid.

For skywave, propagation delay can vary several 10s of microseconds
as the layer height changes. The differential difference depends on
the particular path geometries and is a bit harder to characterize.
If you want propagation delays that vary only by 10s of nanoseconds,
you need to look to WWVB's VLF groundwave signals. Except at sunrise
and sunset, propagation delay is very stable at VLF.

Another substitute that I have used for anhydrous alcohol is the
stuff they sell in auto parts store as fuel line anti freeze. It
has little water if any and is a suitable sub for the drug store stuff
that can be priced high, only because it's sterile. Get the isopropol
stuff. I guess if it had any water in it anyway, it would'nt be a good
fix for fuel line freeze up. If it had any other bad stuff in it, it would
gum up fuel injectors etc. I've used the stuff with no ill effects when
I need an alcohol cleaning agent. Does anyone have any comments or experience
with using fuel line antifreeze in this manner ?

Freon TF, trichlor, or carbon tet can be used to wash off the dirt, though the EPA hates all those cleaning agents. Plain hot distilled water can be used too, though it won't remove grease or oil. The addition of a surfactant like tri-sodium phosphate will help, though the EPA doesn't like that either. Lighter fluid can also be used to remove oily residues, though there's an obvious fire hazard. To remove contact tarnish (assuming silver plating) use a weak phosphoric acid mixture (Tarn-X is a commercial brand). Flush the area throughly with hot distilled water after using acids to clean the part.

You can just use Coca Cola Classic(tm) to clean the switch if you flush throughly with hot water afterwards to remove the phosphoric acid and sugar residues. Don't use Diet Coke(tm), it'll leave a difficult to remove residue.

-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
```

Contents

1.0 What is BASIC Stamp ?
1.1 What is L.O.S.A all about ?
1.2 How can I contribute to this list ?
1.3 Where could I find L.O.S.A ?
1.4 List of contributions.
1.5 Credits and other things.

1.0 What is BASIC Stamp ?

BASIC Stamps are small single board computers (SBC) that run BASIC programs and are made by Parallax, Inc. in US. At first glance, they may seem fairly minimal - and in fact, they are. But with software that fully utilizes all available hardware, the Stamps give you powerful features - without the cost of hardware. Their low cost and simplicity make the Stamps perfect for many prototyping and control applications. And are suitable for electronics hobbyists as well as electronics professionals in many different areas.

1.1 What is L.O.S.A all about ?

I started to compile L.O.S.A because I know there are lots of great ideas and many problems that are solved with the BASIC Stamp and the main purpose of this list is to get an idea of what other people are using their BASIC Stamps for and maybe get some inspiration or hints.

Remeber it's up to all of us if this list are going to be any good and I'm looking forward to receive a description of your application.

1.2 How can I contribute to this list ?

If you have done something with the BASIC Stamp (big or small) that you are willing to tell others please use the form given below and

write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Then e-mail the form to:

cj@algonet.se

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill in
the L.O.S.A form on the Web-page...

==
Title : Logic Rudder [# 001]
==
Date : 950812
Author: Christer Johansson
E-mail: cj@algonet.se

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : LRUDDER.ZIP
URL : Soon to come

Description :

Many of the new and very realistic flight sims available today needs
rudder to let you get full control. This one uses a digital pot from
Xicor (X9104) and 10 other components. Connects to a standard IBM-PC
game port and power is taken from the port.

It uses two micro switches for controlling the rudders left or right
and to indicate when rudders move there is a red LED that lights up
when you press the micro switches and to indicate center there is a
green LED. If you press the both micro swithes the rudder will auto-
maticly return to center position.

There is a trim pot to set the desired step rate from slow to very
fast and the Xicor pot has 99 steps wich gives a fairly resolution.

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : PAGER.BAS
URL : ftp://ftp.parallaxinc.com
-------------------------------------------------------------------------
Description :
```

This program for the Basic Stamp is used to monitor 4 hardware signals. If a change takes place, (after testing for a false trigger) then a cheap 2400 baud MODEM is used to dial into a Telecom Alpha-Numeric pager. It leaves a message which consists of a 2 digit I.D. (01 to 99) followed by the 4 signal levels of pins 3 to 0.

Status of the signal levels message: 0=Low, 1=High. EG: "011110" means Unit "01" has pins 3, 2, and 1 high, and pin 0 is low.

A "Ring-In" feature is also included. By ringing the MODEM for a short period, then hanging up, the Stamp will dial your Pager and report the current hardware status of these four signals.

This program uses about half of the available memory, so if the user wishes to add enchancements such as "Multiple Ring-In's" say within a minute, for a command selection, there is plenty of program space left.

Does anyone have any mods for the ICOM IC-736?

I'm looking for a way to turn the pre-amp back on below 1.6 Mhz.
Icom turns it off even though it the light says it's on.
I would like to listen for some lowfer stations 1750 meter band
(160-190 kc. 1 watt into a 50 ft antenna).

I'm also looking for a way to improve the recieve audio.
The recieve audio sounds flat and distant, lacking highs & lows.
With the notch filter ON the audio sounds a little better,
but it still could use some improvement.

They re-shape the audio through the notch filter,
and it actually has a nicer sound with the notch filter on
(Has more highs & lows).

I had a IC-737 that had the same problem with the audio,
just not sounding quite right.

I am also interested in any other mods for the Icom IC-736.

Please send any replies to yingst@knighted.com

Note: If you post a reply into this newsgroup I probaly wont get it,
my internet provider only holds news for 1 day.

Thank You. Harry N6VUJ

How interesting! Please tell us more, like for instance: Do you use a
telescope or some kind of optics to receive with? Is it useful in daylight or
only at night? What kind of modulation?

You mentioned 40 excess dB. Is this at the 5 mw level? Are you saying you
could reduce the power to 50 microwatts and still have 20 dB excess? Over a
12 mile path? If so, that's pretty impressive...

5388. Photoreceptors for Flying Spot Scanner

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-19 00:00:00 UTC
From: stevem@w6yx.stanford.edu
Message-ID: <48m8od$ggn@nntp.Stanford.EDU>
Source record: 109501

What? A flying spot scanner in today's world!

I was thinking of what I should do with a couple of surplus video camera viewfinders (about a 1 inch video monitor) in my junk pile when it occured to me that they might make an interesting flying spot scanner for viewing or transmitting slides on ATV.

In the old days, they used photomultiplier tubes for the receptor element. I have not done much work with solid state photo sensitive devices so I was wondering what might work best. I am looking at cds cells, photovoltaics, photo transistors and diodes etc. I do not have a good understanding of which might be best in terms of response time, linearity etc. and was wondering if anyone had any suggestions. Is there a device I have overlooked?

I was thinking of 3 devices with RGB filters and one of the many RGB encoder chips to do most of the processing. I will get synch from my ATV camera or test generator to form the raster on the CRT. That will make for nice, in phase, switching between video sources.

Thanks in advance.

Message-ID: <48o0k8$389@rouge.usl.edu>
Source record: 109502

Perhaps I missed a posting on this point, but I think the circulator
(or isolator) has the best benefit NOT of making the transmitter immune
to SWR variations, but in keeping received RF out of the transmitter.
Imagine a paging transmitter on a tower using 152.48 MHz. Now suppose
a competitor locates their 157.74 transmitter on the same tower.
What do you think the 3-rd order mixing product is? Yep, 147.22 MHz.
Since pagers run rather high power, and often use no cavities, they
help us keep our 2m band occupied :-(.

5394. Timecode stuff...

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-20 00:00:00 UTC
From: kyrrin@wolfenet.com
Message-ID: <kyrrin.791.029E669A@wolfenet.com>
Source record: 109375

Hello, fellow hamateurs...

I acquired an interesting piece of gear today. It is designed to receive a signal from the GOES (sp?) weather satellite, supposedly at 468 MHz, extract the timecode info from the incoming Manchester data, and display it on the plasma readout on the front panel.

I've already spoken to the manufacturer (Kinemetrics/Truetime, Santa Rosa, CA) and they're sending me the manual for the thing. I'd very much like to be able to put it into active service in the shack. For the benefit of anyone who might have seen one of these, or may be familiar with it, it is a model 468-DC.

Here's the kicker; I live in an apartment, and would not be able to do anything outside for an antenna array. My question; how powerful is the signal from the bird? The receiver is built in to the unit; all it needs is an appropriate antenna connection, and I see no reason why it wouldn't lock on.

Is there a halfway decent antenna I can use to try this beastie out without alienating everyone in the complex? Being in Washington state, southeast of Seattle, I think I'm in a good spot to pick up GOES West.

Second question; I built the miniature WWV 10 MHz receiver, featured in an issue of 'Electronics Now' a while back. I'd like to build a circuit to break out the 100 Hz(?) subcarrier, and extract the binary timecode data to feed to one of my other TCG's. Suggestions would be most welcome, as my skills in design are somewhat less than my computer skills. ;-)

Comments or assistance would be much appreciated. Thanks!

Hi Dave. This note a followup to the one commenting on laser coms.
Regarding the phase shift on WWVB, I finally phase locked at four times
60 KHz. This allows measurements to be made continuously as the ID phase
shift then gets washed out by the multiplication! Cliff Buttschardt W6HDO

Have a look at Motorola application note AN758. This describes a
1.6MHz to 30MHz 1KW amplifier which consists of a 4-way splitter
4 broadband amplifiers and a 4-way combiner.
With 4 identical amplifiers there is no power dissipated in resistors
in the combiner. Any gain and/or phase errors (including complete
failure of a module) cause power to be dissipated in the combiner.

Dave, your finding that some TV stations "are better than others" as regards color burst frequency accuracy isn't surprising, as most broadcast TV stations these days resync all program material to their local master oscillator, which may not be a rubidium/cesium oscillator and/or may not be maintained to network frequency standards (but are within FCC requirements). IMO without info regarding a particular TV station's master oscillator, you probably can't expect better than 0.1 to 0.01 ppm uncertainty from the color burst signal; relative measurements I've made on some TV stations in my area seem to indicate this as well.

As far as articles pertaining to network color burst generation, I don't have anything specific, but you might want to look in the Journal of the SMPTE (Society of Motion Picture & Television Engineers), particularly in issues dating from 1970 through 1974. I believe it was sometime during this period that the networks began using rubidium oscillators, and I would think that there ought to be an article or two published in the Journal which would be of interest. Hopefully there's a library near you which has the Journal available.

FWIW I own an Arbiter Systems 1011 Frequency Comparator (thanks to Stan Perkins), which was designed in the early '70s to take advantage of the network color burst signals as a reference for calibrating oscillators operating @ the common lab standard frequencies of 100 kHz, 1 MHz, etc. Looking at the manual, it appears to imply that multiplying the color burst

frequency by the fraction 88/63 results in a frequency of 5 MHz, and you might want to try this ratio if you want to experiment further with color burst signals.

The best chemical I have found for removing deposits is "Gunk Carb Medic"
carb. and choke cleaner, available at most auto discount stores. I've
used Tri-chloro (very expensive and an EPA no-no), various alcohols and
acetones, but Carb Medic (at 2 bucks a can) seems to work best. Only thing
is it will eat practically ANY plastic (excluding teflons and their
derivatives) or pertroleum based product. It also has quite an odor, so
be sure to use it in a well ventilated area. The stuff is normally
highly flammable, but to my knowledge does not leave a residue, so it
should be safe for your application.

>a GPS receiver ? Is it usable for this purpose ?

Most are not. Usually there is only a software phaselocked loop with an oscillator in the receiver of at best TCXO accuracy levels. Therefore there is no handy frequency available to tap off a real 10.23MHz signal.

All the satellites are on slightly different frequencies as they reach the receiver due to Doppler shift. Hence the PLL is necessary anyway. So aside from making acquisition faster there is little or no need for a very accurate clock in a GPS receiver even though GPS can be used as a source for a time standard. (And I think there is at least one company making a standard stabilized by a custom GPS receiver.)

If your local TV station uses modern practice and stabilizes their color subcarrier with a rubidium or cesium standard you can get quite accurate results by locally disciplining an oscillator using a phase lock loop to the recovered subcarrier. You divide the subcarrier by 63 and a 5MHz standard by 88 to feed the phase detector for the 5MHz standard. (Erm - at least in the US you can do this. The constants for PAL would be a tad different I suspect. But it should be doable there as well.)

Does anyone have any mods for the ICOM IC-2000H?
I'm looking for a way to turn the AM Detector on above 136 Mhz.
(switch between AM & FM by pressing some buttons)
I would like to listen to some WX Satellites on 137.50 Mhz. AM.

I am also interested in any other mods for the Icom IC-2000H.

Please send any replies to yingst@knighted.com

Note: If you post a reply into this newsgroup I proably wont get it,
my internet provider only holds news for 1 day.

Thank You. Harry N6VUJ

5403. Mods for Icom IC-736

Does anyone have any mods for the ICOM IC-736?
I'm looking for a way to turn the pre-amp back on below 1.6 Mhz.
Icom turns it off even though it the light says it's on.
I would like to listen for some lowfer stations 1750 meter band
(160-190 kc. 1 watt into a 50 ft antenna).

I'm also looking for a way to improve the recieve audio.
The recieve audio sounds flat and distant, lacking highs & lows.
With the notch filter ON the audio sounds a little better,
but it still could use some improvement.
They re-shape the audio through the notch filter,
and it actually has a nicer sound with the notch filter on
(Has more highs & lows).

I had a IC-737 that had the same problem with the audio,
just not sounding quite right.

I am also interested in any other mods for the Icom IC-736.

Please send any replies to yingst@knighted.com

Note: If you post a reply into this newsgroup I probaly wont get it,
my internet provider only holds news for 1 day.

Thank You. Harry N6VUJ

I'm still in the process of insuring that I get to spend a few
hours looking at every article. In the past, there were some
that apparently went to press without me getting a good look at,
especially during the busy conference season when I'm out of the
office. Getting rid of those errors is quite a priority at HQ,
I'm spending a lot more time looking at articles and less time
writing stuff up. (I just tested a 2M directional coupler with
30 dB directivity and realized I designed and etched the circuit
board back in April).

There is still a posting for an Assistant Technical Editor--paying
32-35k. We could certainly use an expert on everything to spot those
technical errors.

5408. Re: QST Nov '95: A Small High-Performance CW Transceiver

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-20 00:00:00 UTC
From: fifield@lan.nsc.com
Message-ID: <9511201211.AA26636@davef>
Source record: 109517

I noticed yet another couple of errors as I laid out my PCB this weekend:

1) U5 (NE5514), no pin number for Vcc - should be pin 4

2) U6 Power pin numbers are reversed. Vcc (+12V connection) should be pin 4
and ground should be pin 11.

3) There are two U6B shown, one of them should be U6C (pins 8,9,10). In fact,
I found it easier to layout the PCB using the op amps in an entirely different
configuration. This is also something that Kanga do on their PCB, so be aware!

Gee, Joanne, been a while since you've been in a TV station I guess.
Almost all TV stations nowadays use frame syncs for signal timing
convergence in plant, and reference those frame syncs to a simple
crystal oscillator, often not even in an oven. The FCC only requires
us to stay within +/- 10 Hz of the defined color subcarrier frequency,
and there's no point spending extra money and effort to do better.

Once upon a time, when frame syncs were horribly expensive, we used
atomic standards to stay in phase with network signals, and networks
used atomic standards too. But those days are long gone (and wouldn't
work today anyway with the networks being distributed by satellite
with the inherent doppler that introduces). A frame sync is 9 chips
today, and any atomic reference you find in a TV plant will only be
a relic.

>power, take the common log and multiply the result by 20.

75.25 db actually. You have to use 2 raised to the 12.5 power since
that's the resolution you actually have, to the nearest half of
one bit beyond the least significant bit. 85 db was a typo. Its still
not enough. A 16 bit sample gives you 99.33 db, and that's better.
But still not enough either if you need high dynamic range. You
really have to arrange for some AGC feedback even with 16 bit samples.

Note: some A/D converters aren't even trustworthy to +/- 1 bit,
so they'd be 2 to the 11th power or 2 to the 15th power for their
true dynamic range. But a good converter has 1 bit more internally
than it outputs so that the least bit is significant to +/- half
of a bit beyond what is output.

True enough, but the relics exist; no reason not to use them.
Channel 5 in Boston uses (in 1994, anyway, last time I checked)
a rubidium standard for its house sync.

5417. Chassis punch for Octal Socket

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-21 00:00:00 UTC
From: FJEX69A@prodigy.com
Message-ID: <48rhji$bg2@usenetw1.news.prodigy.com>
Source record: 109380

I'm upgrading the final amp in my Swan 270B to a 6146B from a 6LQ6. I got a nice tube from Red China and a ceramic octal socket and went at it soldering iron a-smokin'.

The reason for this project is that 6LQ6's go for $42 each, when you can find them but Commie 6146B's go for $12. Also the 6146B has 20% more plate dissipation, which is dearly needed in this design.

What I did not foresee is that the original hole for the 9-pin socket is too small to accomodate the octal socket. I don't want to use a crude method to modify the chassis so I am hoping to find a kindly ham who will lend the proper tool for this job. I will bear all expenses and pay a small fee to such an individual.

Thank you- AC4AQ

PS I know the heater current is different- thanks.

5420. antenna switch reactance

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-21 00:00:00 UTC
From: paul1@wizard.ucs.sfu.CA
Message-ID: <9511210452.AA08671@wizard.ucs.sfu.ca>
Source record: 109383

I am in the process of doing a bit of antenna experamenting and in order to make antenna changing easier I built a coax switch in a small metal box and some bnc's. Not suprisingly, the box introduces enough reactance to effect the tuning of the individual antennas. All the antennas a fed with 300ohm twinlead with individual tuners. I'm wondering if I should attempt to tune out the reactance in the box or just leave well enough alone and simply adjust the tuners to compensate.

Suggestions will be greatly appreciated.

:
: tnx
:
: de daveaa1a@aol.com

Well, forget color burst. Broadcast network bursts once were NIST
traceable but no longer. NIST bungled it and dropped the program.
Pissed me off. I had a proportional crystal oven time base which
could lock to it. It fed a simple synthesizer to derive standard
frequencies. Sheesh, anyone with a color TV once had a NIST traceable
frequency reference.

At present there really is no low cost easy way to reference a NIST
traceable standard. WWVB is ok if you live within its coverage area but
it is pretty much worthless on most of the east coast. WWVB Reception is
particularly bad in urban areas with high RFI levels. NIST now recommends
GPS but you need a special GPS receiver. Most of the consumer models
don't cut it. Omega and Loran are ok if you have the gear ...

However here is something that might be of interest:

Hi All:

I have a quick question. How does the Ramsey shortwave
receiver kit stack up as far as sensitivity and
selecttivity compared to MFJ's 8100K. Would the Ramsey Kit
be a nice set to build and listen to?

Gary-

5428. Tek 604 CRT Display Diagram?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-21 00:00:00 UTC
From: galen@lamar.ColoState.EDU
Message-ID: <48t6n1$vra@lamar.ColoState.EDU>
Source record: 109391

I have a Tektronics model 603 CRT display unit. It has a little problem with with it's -30 volt supply (it's only -25.6 volts, manual sez -30 exactly) and the manual I have is a poor photocopy, missing some horizontal lines, etc.

Does anyone know where to get a better copy or even a real manual? I only need the diagram marked 'Low Voltage Power Supply/Regulators' and is a schematic of same. The bottom says (I think): "603/604 Rev H June 1976'.

havin' fun,

Yes, and the image rejection on the 800-999MHz band is so poor
that you can receive the "blocked" part of the 800MHz band by
tuning the radio to (desired frequency) + 46.1MHz.

: >
: > I'd also like to get a general feeling for what people think about the
: > Standard brand.
: >

I like it's size (not too big, not too small). The DTMF encoder
allows direct entry of digits 0-9,#, and *, but not A,B,C, or D.
You can program these digits into one of six DTMF sequence memories
though.

I've had mine for several months. Works fine, but the tiny
"3-band" antenna supplied doesn't work worth a darn on 2-m.
And 35mW on 1280 is useful for only the most local 1280
repeaters (and as a signal source for testing).

I loaned or lost my octal punch long ago, you might have better luck
tracking down a local electrician. Most of them have a good
array of punches(the more inovative will have hydrolic(sp) punches)
and will shouldn't charge too much to punch it. I bet if you
check on the air, you even have some hams locally who are
electricians.
Just a thought.

I find them at hamfests and swap meets. Ask around on 2-meters. There are a lot of old-timers still active who have tons of this type of part sitting in boxes, drawers, and jars in their shacks, waiting for someone to put them to good use.

You might find junked-out or needing-to-be-junked-out <G> rigs from yester-year that use them. The PA tune and load caps are usually large, and the driver peak/tune caps are usually small. They nearly all have 1/4" shafts for knobs.

I have a bunch of them in my junkbox, but I have no idea what any of their values are, as most are unmarked. If you have a way to measure them, I'll trade them to you for other parts, to be determined (I'm always needing something or other).

>
>Zack zlau@arrl.org.

Zack,

Why doesn't the ARRL make use of the FREE technical ability of the Technical Directors and the amateur population that works in the industry? That would radically reduce published errors without any cost penalty. HQ will likely have a difficult time hiring a reliable technical expert for the salary you listed, when industry pays over twice that amount!

It is much better to have consensus from several independent sources. Sole sources are almost never reliable for technical data. No single person is error free or catches every mistake! Only a fool or ego-maniac would believe otherwise.

Ceratinly *a few* technical errors are simple and stand out, even a single reliable source could catch those errors. But most technical articles require ****GROUPS***** of experienced reviewers, NOT the single source commonly depended on. The League doesn't need to do the work or even pay for the help. The staff simply needs to learn how to allow and encourage people to help. Resources are available if the staff uses them.

QST and the ARRL Handbooks are certainly the most error free Amateur type publications available. But in my opinion accuracy is slipping. Things seem to be slowly shifting towards being "just another publishing house" and away from reliable technical information.

If it really is a priority to get rid of technical errors, GL. I hope egos don't get in the way.

Back 25 years ago while ain school, we had some "BK" flying spot
scanners that we used to set up TVs. They used "slides" about 4"
square. Any modern photransistor should work. What will "kill"
the project is the phospher decay time. The BK scanners had a
purple phospher, I called the comapnay to find out why(inquiring
minds and all), and was told that that phospher(and I can not for
love nor money remember the P#) had almost no decay time. This was
to prevent any residual(sp) light from messing up the image.
A standard TV crt has a moderate decay, this will fill in any
black areas. It seems that you could use a P7 scope tube(yea I know
how difficult it is to get sweep voltages high enouge to operate
an electrostatic sweep, current is easier to get these days
than voltage) and a filter to remove the long persitance glow.
I think the fast phospher in a p7 is purple(maybe the same right) and

the long persitance phospher was greenish/yellow.(it has be at least
20 years since I last played with p7 crts for wefax/sstv)
I would be more tempted to just get a "cheap" camera(either bw ccd, or
find a modern camcorder with a color ccd pickup) and go that route.
It would be cheaper, faster and probably work better.
I am a TV engineer at the University of Kentucky and I have trouble
excited about ATV. I can reach the whole US woht about 50 watts...
into our 6.1mtr Ku uplink. I feel kind of sorry for some of our local
atv'ers, they run 75-100watts and get about 10-15miles(in the winter,
after the 440 eating trees lose their leaves that increases somewhat).
Good luck

>Most are not. Usually there is only a software phaselocked loop with an

Most are not suitable because they don't have 1 pulse per second (1 PPS) outputs.
However, 1 PPS outputs are available. For example, the Motorola Oncore
engine has 1 PPS as an extra cost option.

>oscillator in the receiver of at best TCXO accuracy levels. Therefore there is
>no handy frequency available to tap off a real 10.23MHz signal.

You don't need to tap off a 10.23 MHz. signal. What you do is phase lock
a crystal oscillator to the 1PPS signal by dividing the oscillator signal
down to 1 Hz. and comparing to the 1PPS signal. The accuracy you get is
dependent on how stable your oscillator is, what the time constant of the
phase locked loop is, and the resolution of your phase detector.

In the Hewlett-Packard GPS timing receiver we make at this division, we
approach an accuracy of 1 part in 10^12 for 1 day averaging.

If you just want to check the accuracy of your counter, simply measure
the period of the 1 PPS output with averaging turned on. You can adjust your
counter's timebase until it reads exactly 1 second.

>All the satellites are on slightly different frequencies as they reach the

>stabilized by a custom GPS receiver.)

Yes, a fellow from here left and started a company to do that.
Theoretically, it should be better.
The jury is still out on the merits of that architecture.

>
>If your local TV station uses modern practice and stabilizes their color
>subcarrier with a rubidium or cesium standard you can get quite accurate results

That "modern" practice was discontinued at least 10 years ago.

What about skip? Say R1 is one hop and R2 is two hops...

Or the height the hop's are occuring from changes..

Or one receiver is really receiving the signal the "long" way
around the planet..

I'd guess that if you look close and long enough you might see
almost anything for the Tpropdelayvariation.

5443. Ferrite antennas in Pager receivers

I have seen this but it still leaves the question: WWV issues a signal.
At the start of a certain tone my two clocks, no--call them triggers in
this context, when my two triggers receive this tone they send a logic
pulse. The two receivers are different distances from WWV (or WWVH or WWVB
whatever). Say receiver R1 is 100 miles closer to WWV. Receiver R1
triggers at T0 receiver R2 triggers at T0 + Tpropdelay100miles +/-
Tpropdelayvariation. What is Tpropdelayvariation? Is it nanoseconds or
microseconds? Given my locale the distance the signal must travel is much
greater than the difference between the two receivers. I would expect a

very small variation. The variation from one trigger tone from WWV to the next may vary much more due to the long path but the variation between my two receivers on the same trigger should be small.

While not pertinent to the main question above --The statements:

"The frequencies as transmitted are accurate to about 1 part in 100 billion (1 x 10^-11) for frequency and about 0.01 ms for timing. The day-to-day deviations are normally less than 1 part in 1,000 billion (1 x 10^-12)."

leave me somewhat confused. Are the timing indicators allowed to drift +/- .01ms from one signal to the next at the transmitter? If the daily deviations are 1 in 1000 billion (I assume this is on frequency) why so inaccurate?

>Additionally, IMO one needs to consider the effect of local clock
>oscillator drift at each site during periods of poor reception; for

Yes! Am planning to build the local clocks in themos bottles with small light bulb for heating element. Should be able to hold better than +-1 degree C. Will see what this does for drift.

>If the 1 millisecond timing uncertainty quoted above is not "good enough"
>for your purposes, consider using the time code embedded in the 60 kHz
>WWVB
>signal. As regards the the WWVB time code accuracy, NIST Special
>Publication 432 states that "The BCD time code can be received and used
>with an accuracy of approximately 0.1 ms."

There are multiple freqencies from each station. Is this one known to be better than the others in terms of reception? Another post said to use the ground wave signal at VLF. I think this was what he was refering to. Will this reach from Colorado to central Arkansas?

Thanks for the thoughts!

5445. Re: Ramsey Kits..worth the money?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-22 00:00:00 UTC
From: QRP%mimi@magic.itg.ti.com
Message-ID: <48vjbb$dpq@mksrv1.dseg.ti.com>
Source record: 109408

I built the Ramsey 20m QRP transmitter. One of the transistors was defective right out of the package. The power output was claimed to be one Watt, but in reality, it was more like 350 - 400 mW. Other hams in D/FW have echoed the same finding (low output). It worked as it should, except for the lower-than-advertised power output. I don't like their use of RCA connectors for everything, although you could change the connectors if you don't use their enclosure set.

I also built the Ramsey 40m receiver kit. Junk! It drifts like mad and never does stabilize. The audio output is weak, even using a set of headphones like they suggest.

All in all, I would suggest going another way.

For roughly the same money as the two Ramsey kits and their enclosure sets, you can buy the NN1G superhet transceiver kit, with vfo control on transmit and full break-in. This is a great little rig and works far better than the Ramsey junk could ever dream of. I built this one a couple years ago. Mine was featured in the July, 1994 issue of QRP Quarterly.

I hate to bash anyone, like I'm doing to Ramsey now, but I honestly do not feel their stuff is worth the time and effort you'll put into it, much less the money. There are other, better alternatives...

Hi!

Does anyone have any suggestion on how to build a 1296MHz VCO?
I have about one hundred BB809 varactor diodes. Will they work (good)
for this frequency?
I also have a bunch of MSA-0386 and MSA-0486 MMIC's. Can i use them
for an oscillator?

Thanks for any help!

Source record: 109412

Greetings all,

A quick question.... I have an older Icom HT, whose exact model I cannot remember right now. I really don't need it for use on 2m 144 MHz + that it is set for. Is there any way to take a full 100 MHz off of this unit and still have it work? Could it be modified to transmit in the 44+ MHz range or will and such modification completely destroy the transmit ability of the radio.....

Just thinking about the possibility of this sort of thing..... Any advice would be most appreciated.....

Burt Fisher <k1oik@ccsnet.com> writes:
> Frequently I hear hams say, THE name HERE is_____.
>How often do you say when you meet someone (assuming your name
>is Charlie), THE name HERE is Charlie? You never do that right?

It's a different culture, Burt, and you're experiencing culture shock. Amateur Radio has been around a lot longer than you have, and it has developed its own "code of conduct" and a particular way of speaking. In Mexico, one does not say "My name is ____" -- to do so would be considered an EXTREMELY impersonal statement! One says instead "I am called ____" -- and that's just the way it is.

You seem to be ridiculing a common practice merely because it sounds impersonal to you. From the other point of view, you are attempting to use face-to-face speaking conventions when you are communicating with voice only, and that sounds just as strange to many "oldtimers" as the way it's done now sounds to you.

Remember that for the most part, radio communication is just barely interactive; while you are talking, there is no feedback from your listener(s). Don't expect to be able to use the same conversational style in all situations. For instance, how often do you begin a short monologue with the phrase "Three minutes ago, so-and-so said:" and a direct quotation? How often do you punctuate your sentences with "emotion" indicators? Be flexible. When in Rome, do as the Romans do. Don't flame them lest you be burned yourself. (Oh, sorry. Too late.)

FWIW the two frequencies used are 468.825 MHz and 468.8375 MHz for the GOES West (135 deg W) and the GOES East (75 deg W) satellites, respectively.

According to NIST Special Publication 432 (Revised 1990), the typical received power with an isotropic antenna (0 dBi) is -131 dBm.

> Is there a halfway decent antenna I can use to try this beastie out without
> alienating everyone in the complex? Being in Washington state, southeast of
> Seattle, I think I'm in a good spot to pick up GOES West.

GOES West would probably be best for you. As far as antenna choice goes, I'd suggest going w/ a right hand circular polarized type, unless you can tolerate the polarization losses from a linearly polarized type. Depending on the coax type and length you're planning to use, you may want to consider a quadrifilar, a circularly polarized Yagi, or a helical antenna. You may have to consider using an LNA at the antenna if you're stuck w/ a physically small (low gain) antenna & can't make threshold at the receiver. If you're willing to build your own antenna, consider some of the 70 cm designs mentioned in the various ARRL publications & scale accordingly.

> Second question; I built the miniature WWV 10 MHz receiver, featured in an
> issue of 'Electronics Now' a while back. I'd like to build a circuit to break
> out the 100 Hz(?) subcarrier, and extract the binary timecode data to feed to
> one of my other TCG's. Suggestions would be most welcome, as my skills in
> design are somewhat less than my computer skills. ;-)

One approach you could try is to use a 567 tone decoder to detect the 100 Hz pulses from the received baseband signal, and some logic to convert the data to the format you need for your TCG (it's a bit tough to get more specific w/ out knowing what format your TCG expects). You can find enough info on how to setup a 567 in the data sheets from the vendors who make them (Signetics, Nat'l Semi, etc.).

The 100 Hz tones used in the WWV/WWVH broadcasts are a variation of IRIG-H timecode, and the format is described in NIST Special Publication 432, so you might want to get a copy from your local GPO bookstore or try http://198.87.193.150/~clocks/clocks/clocks.html - the Web site has what I'll call an "unofficial" HTMLized version of NIST Special Publication 432. The tone decoder (and your receiver's RF/IF bandpass, plus propagation delays) will introduce delays which may or may not be tolerable for your use, so keep this in mind.

Hope this helps, & good luck -

}-- James Dugal, N5KNX Internet: jpd@usl.edu

So far I have been lucky, every place our club has sites,
all transmitters are required a circulator and cavity after it.

Circulators are non-linear devices too and the cavity helps keep them
from saturating and generating their own harmonics!

I have heard some horror stories about "paging only" sites - And the
attitude: "We don't create any intermod at all." Hard to
tell without a local receiver!

Yes, I regret to say that we fell behind schedule. However, we are catching up. You should have received your September issue by now, or within the next few days at the latest (in North America, anyway). The October issue preview copies have come back to HQ from the printer, so those should be arriving in your mailboxes over the next couple of weeks. The November issue is at the printer and should be hitting mailboxes shortly after the October issue, and the December issue will go to the printer in early December for late December/early January delivery. Following issues will continue to creep back toward the normal schedule until things are back in order.

I apologize for the inconvenience and the delays. We'll get it fixed.

At least two companies that I know of offer GPS receivers with internal (or external) disciplined oscillators. The versions I've discussed with them were needed in order to provide a 10 MHz reference, but I'm sure other frequencies are available.

The real question is, how much do you want to spend on this? The cost varies tremendously as a function of the inherent stability of the disciplined oscillator. We use these units to phase lock the cariers of banks of transmitters, and there really is no good substitute when multiple transmit sites are involved. That's particularly true given that we require a relative accuracy between transmit sites of < 1Hz at 2.5 GHz, and that the installations are often in countries where other on-air references are not available.

Unfortunately, the units we use typically sell for upwards of $4,000.00. This cost would come down somewhat if a less-expensive oscillator was substituted, but I suspect the bottom line for anything suitable for use with a counter would still run at least $2,500.00.

Well, the answer will depend on the ionospheric conditions at the time, and
to some extent whether or not both sites are using the same receiving
frequency. I don't think you can count on variations of less than several
microseconds under relatively stable ionospheric conditions. Ionospheric
conditions near sunrise and sunset are liable to degrade the variations
significantly.

My intent of quoting from NIST Special Publication 432 was to give an order
of magnitude bound on the timing uncertainty from a credible government
publication without having to resort to doing a ionospheric propagation
study specific to your situation. Unfortunately, I didn't expess this
sentiment in my previous posting.

> While not pertinent to the main question above --The statements:

Your question really should be posed to the folks @ NIST. I would suspect that their time code generator hardware has some inherent jitter (or was specified as such during design) which NIST has deemed tolerable relative to propagation variations.

> >Additionally, IMO one needs to consider the effect of local clock

This approach is IMO the right one; however, depending on the environmental extremes your oscillators will experience, you may have to consider a secondary oven surrounding your thermos bottle or at least some supplemental insulation to keep the oscillators within stability requirements.

>
> There are multiple freqencies from each station. Is this one known to be
> better than the others in terms of reception?

The choice of "best" WWV frequency depends on the propagation conditions between Fort Collins and your site, which will vary with time. For example, where I live there are periods where the best WWV signal is found at 5 MHz, other times at 10 MHz, still other times where the WWVH signal is almost overwhelming the WWV signal. Local RF noise sources may be strong enough to render a given WWV frequency useless as well. As always, YMMV.

> Another post said to use the ground wave signal at VLF. I think this was
> what he was refering to. Will this reach from Colorado to central Arkansas?

Yes, the 60 kHz WWVB signal should be receivable in Central Arkansas; I think the received electric field strength should be on the order of 300 to 400 microvolt/meter (this is from a rough mental picture of the field intensity curves, and of course corrections are welcome). Of course, manmade interference could be a problem so you might want to do a bit of investigation w/ a good ELF receiver before committing to the WWVB approach.

This may have been mentioned by the time I post this, but if the WWVB approach looks feasible, you might want to look at the January thru March

1994 issues of 73 magazine, where a WWVB receiver, frequency comparator and ovenized oscillator are described under the title of "Using the World's Most Accurate Frequency Standard." Other sources of relevant information can be found in the March 1976 issue of Ham Radio magazine, and in the August & Sept. 1973 issues of Radio-Electronics magazine.

I apologize if I am posting this to the wrong newsgroup but I am in desperate need of advice. I have a Pioneer KE-A530 car radio + cassette that my friend removed from his car a while ago. I am not sure which wires go where because I don't have the manual anymore and there is no indication on the radio as to what each wire is. I would appreciate if any of you could tell how to make the connections (i.e. which is PWR, GND, speakers, etc.).

The wires are in three "bunches":

Bunch 1: blue
black

Bunch 2: green/black (2 wires)
gray/black (2 wires)

Bunch 3: black (this is definitely a GND -- connected to case)
red (has a 0.5 Amp fuse on it and a little box)
yellow
orange (this must be PWR -- it has a 0.5 Amp fuse)

I really appreciate your help. I reply to my personal e-mail address, as I do not read this newsgroup regularly.

Thank you,

5461. Re: Pioneer KE-A530 question

My experience, although much more limited than Tom's, is the same.

>The main worry is the ESR of the capacitor causing internal heating and
>poor regulation. I have never found any energy storage cap to be a
>problem, even up to the 25 kW plate input power level.

Equivalent series resistance (ESR) could be a problem. Offhand, I don't know what the typical ESR of a photo flash cap is, or an oil-paper for that matter. The concern is high ripple normally encountered in capacitor input power supply filters. In effect, the capacitor is receiving large slugs of current at a 120 Hz rate. This (RMS) current (squared) times the ESR gives the power dissipated in the capacitor. Of possible concern too is the peak charging current. Typically, some type of inrush current limiting is used with capacitor input filters.

In my current application, a ~3500 VDC 1A supply, I'm using a 47uF 5000 V photoflash cap. However, I'm also using a resonant choke input to limit the ripple and improve regulation. I don't use much bleed current and with electronic bias switching in the amplifier, the voltage does soar some during standby. The ripple current during this time is low however, so there is minimal heating.

>I would just go ahead and use them. Be cautious of one thing, the terminal
>to case voltage rating generally does not allow for series connections
>unless special precautions are taken.

This is another concern of mine. I mounted my capacitor using Teflon insulation and let the case float.

73, Wes

Source record: 109330

Re the comment on the Ramsey QRP rigs--a few years ago I testedthe 40M rig a friend built, looking at the output on two communications monitors and a "real" spectrum analyzer by Hewlett Packard. All three agreed: the second harmonic was 20 dB below the carrier, which failed by 10 dB to meet the minimum FCC requirement of at least 30 dB (which rises to 40 dB for rigs over 5 watts output). I added in a supplemental filter, 5 element Chebyshev, cutoff 7.5 MHz, 0.1 dB ripple, and now the second harmonic is 51 dB below the carrier; insertion loss dropped the power from 1.6 to 1.53 watts, hardly excessive.

The stock filter in the 40M Ramsey has 3 elements. Anyone knowledgeable about filters will instantly realize that using a 3 element filter on a Class C amp is begging for trouble with excessive harmonic levels at the output. (My article on this subject will be in the January issue of the QRP Quarterly).

You get what you pay for!
Consider the price, the quality is comperable.
I have several Ramsey kits that I have built, some are great, some not
so great, but dollar for dollar, you can't buy the components
wholesale cheaper, thus buy the kit and mod it to your own specs.

(lots of deletions)

Geez OM, how much accuracy do you need in knowing the value of a variable capacitor? You can certainly measure them to plus/minus 20-percent, or better, just by winding a coil according to a reasonably accurate inductance calculation, put it in parallel with the capacitor and measure its resonant frequency with a calibrated receiver. Isn't that good enough for almost any purpose?

I have some "standard" coils I wound on stable forms and measured their inductances with a borrowed meter. Now I can measure capacitance and inductance within 5-percent, or better, using the same technique. Maybe you could find a local ham who could take your unknown coils to his work place at a commercial, or university, lab and put really accurate values on them for you.

73, and good luck!

The root cause of this problem are the 'original' postings of one BURT FISHER.
His garbage gets replied to by others who inadvertently post to all the
newsgroups the original spammer included in the distribution list.

In the future forward a copy of spam messages from Burt Fisher to the
postmaster at his service provider. Fisher's address is:
k1oik@ccsnet.com therefore you can forward his crap back to place it came
from at postmaster@ccnet.com.

If enough of us do it he will get tired of it and take steps to stop it.
There is no need to even write anything on the forwarded message. They
know who Burt Fisher is, do you think your the first one to complain!? :)

Aside from being a processed nuclear survival food, spam has its own endearing definition as it related to the Internet.

"Spamming" is when a message is posted to serveral, even all, newsgroups at once. Prime examples of spamming occur when some goober posts a "Make 20 Zillion Dollars by Picking Your Nose" post to every single newsgroup in existence. Then, in each of those newsgroups 50 people post a response saying "I picked my nose and only made $.73 you &***#$%!!!!". Most usenet programs will then post that reply to every group the original post appeared in.

I notice that I am posting this response to all the rec.radio.xxx groups. Since I don't know where this thread originated, I'll leave it that way....and now I too have become a "spammer"!!!

Hope it is now clear as mud!

It has been a while since I've worked with extremely accurate time standards, but here is the situaion as well as I can remember. The time standard is based on a series of cesium-beam oscillators (or atomic clocks) that use some sort of intelligent averaging to feed the master time standard oscillator.

It should be obvious that it would be fairly easy to lock the frequency of the transmitter to this time standard. It is just annother oscillator.

The "time burst" is an audio signal that has to be detected. That means that the audio has to rise to a detectable level and that is a function of the audio frequency, not the time standard or the transmitter frequency. 0.01 ms seems incredibly accurate in this context. Does anyone know what WWV's highest audio frequency is in the "time burst" ? What does Nyquist have to say about this?

That is why, for any kind of accurate time, you need to keep your own local standard and use WWV, WWVH or WWVB as corrections rather than primary frequency sources.

You might try this as a quick and dirty fix: in my commercially-made antenna switch box there is a 10pf capacitor from the output connector to ground for just that purpose. Your box will need a different value no doubt, so a variable might be a good choice. If that doesn't fix it, don't lose a lot of sleep over it. Assuming your leads are all fairly short, the amount of reactance introduced won't matter much.

I loaned or lost my octal punch long ago, you might have better luck
tracking down a local electrician. Most of them have a good
array of punches(the more inovative will have hydrolic(sp) punches)
and will shouldn't charge too much to punch it. I bet if you

check on the air, you even have some hams locally who are
electricians.
Just a thought.

>Most are not. Usually there is only a software phaselocked loop with an

Most are not suitable because they don't have 1 pulse per second (1 PPS) outputs.
However, 1 PPS outputs are available. For example, the Motorola Oncore
engine has 1 PPS as an extra cost option.

>oscillator in the receiver of at best TCXO accuracy levels. Therefore there is
>no handy frequency available to tap off a real 10.23MHz signal.

You don't need to tap off a 10.23 MHz. signal. What you do is phase lock
a crystal oscillator to the 1PPS signal by dividing the oscillator signal
down to 1 Hz. and comparing to the 1PPS signal. The accuracy you get is
dependent on how stable your oscillator is, what the time constant of the
phase locked loop is, and the resolution of your phase detector.

In the Hewlett-Packard GPS timing receiver we make at this division, we
approach an accuracy of 1 part in 10^12 for 1 day averaging.

If you just want to check the accuracy of your counter, simply measure
the period of the 1 PPS output with averaging turned on. You can adjust your
counter's timebase until it reads exactly 1 second.

>stabilized by a custom GPS receiver.)

Yes, a fellow from here left and started a company to do that.
Theoretically, it should be better.
The jury is still out on the merits of that architecture.

>
>If your local TV station uses modern practice and stabilizes their color

At least two companies that I know of offer GPS receivers with internal (or external) disciplined oscillators. The versions I've discussed with them were needed in order to provide a 10 MHz reference, but I'm sure other frequencies are available.

The real question is, how much do you want to spend on this? The cost varies tremendously as a function of the inherent stability of the disciplined oscillator. We use these units to phase lock the cariers of banks of transmitters, and there really is no good substitute when multiple transmit sites are involved. That's particularly true given that we require a relative accuracy between transmit sites of < 1Hz at 2.5 GHz, and that the installations are often in countries where other on-air references are not available.

Unfortunately, the units we use typically sell for upwards of $4,000.00. This cost would come down somewhat if a less-expensive oscillator was substituted, but I suspect the bottom line for anything suitable for use with a counter would still run at least $2,500.00.

>Steve Muther WF6R

Back 25 years ago while ain school, we had some "BK" flying spot
scanners that we used to set up TVs. They used "slides" about 4"
square. Any modern photransistor should work. What will "kill"
the project is the phospher decay time. The BK scanners had a
purple phospher, I called the comapnay to find out why(inquiring
minds and all), and was told that that phospher(and I can not for
love nor money remember the P#) had almost no decay time. This was
to prevent any residual(sp) light from messing up the image.
A standard TV crt has a moderate decay, this will fill in any
black areas. It seems that you could use a P7 scope tube(yea I know
how difficult it is to get sweep voltages high enouge to operate

an electrostatic sweep, current is easier to get these days
than voltage) and a filter to remove the long persitance glow.
I think the fast phospher in a p7 is purple(maybe the same right) and
the long persitance phospher was greenish/yellow.(it has be at least
20 years since I last played with p7 crts for wefax/sstv)
I would be more tempted to just get a "cheap" camera(either bw ccd, or
find a modern camcorder with a color ccd pickup) and go that route.
It would be cheaper, faster and probably work better.
I am a TV engineer at the University of Kentucky and I have trouble
excited about ATV. I can reach the whole US woht about 50 watts...
into our 6.1mtr Ku uplink. I feel kind of sorry for some of our local
atv'ers, they run 75-100watts and get about 10-15miles(in the winter,
after the 440 eating trees lose their leaves that increases somewhat).
Good luck

}-- James Dugal, N5KNX Internet: jpd@usl.edu

So far I have been lucky, every place our club has sites,
all transmitters are required a circulator and cavity after it.

Circulators are non-linear devices too and the cavity helps keep them
from saturating and generating their own harmonics!

I have heard some horror stories about "paging only" sites - And the
attitude: "We don't create any intermod at all." Hard to
tell without a local receiver!

>received accuracy is far less due to various propagation effects. The
>usable received accuracy is about 1 part in 10 million for frequency (1 x
>10^-7) and about 1 ms for timing."

I have seen this but it still leaves the question: WWV issues a signal.
At the start of a certain tone my two clocks, no--call them triggers in
this context, when my two triggers receive this tone they send a logic

pulse. The two receivers are different distances from WWV (or WWVH or WWVB whatever). Say receiver R1 is 100 miles closer to WWV. Receiver R1 triggers at T0 receiver R2 triggers at T0 + Tpropdelay100miles +/- Tpropdelayvariation. What is Tpropdelayvariation? Is it nanoseconds or microseconds? Given my locale the distance the signal must travel is much greater than the difference between the two receivers. I would expect a very small variation. The variation from one trigger tone from WWV to the next may vary much more due to the long path but the variation between my two receivers on the same trigger should be small.

While not pertinent to the main question above --The statements:

"The frequencies as transmitted are accurate to about 1 part in 100 billion (1 x 10^-11) for frequency and about 0.01 ms for timing. The day-to-day deviations are normally less than 1 part in 1,000 billion (1 x 10^-12)."

leave me somewhat confused. Are the timing indicators allowed to drift +/- .01ms from one signal to the next at the transmitter? If the daily deviations are 1 in 1000 billion (I assume this is on frequency) why so inaccurate?

>Additionally, IMO one needs to consider the effect of local clock
>oscillator drift at each site during periods of poor reception; for

Yes! Am planning to build the local clocks in themos bottles with small light bulb for heating element. Should be able to hold better than +-1 degree C. Will see what this does for drift.

>If the 1 millisecond timing uncertainty quoted above is not "good enough"
>for your purposes, consider using the time code embedded in the 60 kHz
>WWVB
>signal. As regards the the WWVB time code accuracy, NIST Special
>Publication 432 states that "The BCD time code can be received and used

There are multiple freqencies from each station. Is this one known to be better than the others in terms of reception? Another post said to use the ground wave signal at VLF. I think this was what he was refering to. Will this reach from Colorado to central Arkansas?

Thanks for the thoughts!

Hi Chuck,

I use the incorrect type of capacitors all the time here! They work fine and I have never recorded a failure. I've used dozens of them over the last 20 years! Perhaps they shouldn't be used in commercial service, but in amateur service they are, in my experience, perfectly fine.

The main worry is the ESR of the capacitor causing internal heating and poor regulation. I have never found any energy storage cap to be a problem, even up to the 25 kW plate input power level.

I would just go ahead and use them. Be cautious of one thing, the terminal to case voltage rating generally does not allow for series connections unless special precautions are taken.

> it that way....and now I too have become a "spammer"!!!

Not really. You have posted 'velveeta' (Vegetarian spam).

The difference is that velveeta is crossposted (note the newsgroup line). On the internet, this message will cross the backbone once, and be stored on the ISP host harddrives once, with references to the crossposted newsgroups. It can't even really be called velveeta because you were answering a valid question, even if it was off-topic for the newsgroup in question.

Spam is a message, usually commercial in nature, that is posted once for every newsgroup. In this case, the same message will cross the backbone and be stored on the harddrive once for each newsgroup, resulting in massive waste of bandwidth and disk space.

Internet lore: the term was derived from the Monty Python skit, were 'spam' was said/sung numerous times. It was a really funny skit, too.

Hope this helps.

Where are you at? I have a complete set near Atlanta.

I've done similar changes in my T4XC, the neutralizing circuit and grid capacitance needs modification, as well as bias system. Funny, in my Drake the sockets bolted right in, but then they were American made!

I suppose theoretically, if you *really* had to, you could probably do it and make it work, but to be truthful,
it would be a royal pain in the ass, and not really worth the effort. You'd be changing just about every
component on the board, so you would probably be better off just getting a different radio. See if you can
find someone to do a swap with or something like that.

5489. Code practice oscillator?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-24 00:00:00 UTC
From: n2mcs@aol.com
Message-ID: <493ksq$44m@newsbf02.news.aol.com>
Source record: 109352

Hello. I am going to attempt to design a keyer (based on one of the curtis ICs) with a built in code practive oscillator. The keyer is rather simple, as I have the information I need.
However, I don't know how to go about building the oscillator. Someone mentioned to me that I could build a simple osc. using a 555 timer IC. I can imagine how this is possible, but can't seem to figure out the details. I want a reliable osc. with variable pitch. The audio amp part I can handle (yet another IC) I prefer an IC approach because it tends to look nicer (I like to show off my work, who doesn't?) But if you have a simple and reliable design with other methods, I am all ears!

Thanks for everyones help in advance.

I am trying to build an array of patch antennas for 435 MHz. Where could I find more information on the dimensions, etc. I would like to use double sided PWB material like Duroid Ro4000 series and would like to etch the antenna right on the board without using spacers. There was a recent article on QST on building a patch antenna for GPS, but very little info was given on how he arrived at those numbers.

thanks & 73's

>Lucas Gertenbach
>lukes@iaccess.za

I am also interested in any information on this topic.
I have collected a few hard to get articles on the subject
over a number of years. Philips seems to have pioneered the
ferrite material for them, and now Siemens, TDK, and Neosid
also make antenna ferrites. In the USA, Fair-Rite Products
#68 is the best I've tried. Ceramic Magnetics in NJ is nice
in that they can machine the ferrite to any shape you want.
You might try reading about HF ferrite loopstick antennas
in the ARRL Antenna Book. The VHF ones in pagers work on
the same principles, just lower permeability and a lot
fewer turns, of course. I once built a 6 meter transmitter
the size of a pack of chewing gum using a ferrite rod antenna.
It had a range of several hundred meters with .1 watts.
The "coil" was a slit piece of copper tubing with a bunch
of capacitors across it to resonate the one "turn".

Which is why we try to quickly route articles through several
staff members. While I don't care if it takes a year of more
to publish my articles, many authors are concerned about how
long it takes for their stuff to appear in print.

Some stuff does have a short shelf life--we do know that
Radio Shack likes to change its assortment of parts. But,
is that grounds for rejecting an article that someone has
spend a lot of time and effort developing?

>Ceratinly *a few* technical errors are simple and stand out, even a single
>reliable source could catch those errors. But most technical articles
>require ****GROUPS***** of experienced reviewers, NOT the single source
>commonly depended on. The League doesn't need to do the work or even pay

>people to help. Resources are available if the staff uses them.

Looks like we need to hire an expert on managing volunteer labor.
How do you get them to give the volunteer work you hand them top
priority? People change jobs and they seemingly vanish...

Its also an interesting problem to decide which expert/experts
are right. I was surprised to find out that the K2RIW 432 MHz
parallel4CX250 amp was actually rejected by Ham Radio.

>I do not read this newsgroup regularly.
>
>Thank you,
>

I'll try, but dont blame me if it blows up!!!. Ok...start with bunch 3. The black wire goes to battery negative terminal, or chassis ground. The red wire with fuse holder and box (noise filter, likely) goes to ignition ACC ON. T The yellow wire is used if you want to send a signal to an auto amplifier (external power amp, subwoofer, etc) or a power up/down automatic retractable antenna. The orange wire might be to control a clock if the radio has a clock built in. Orange wire would then go to the battery and the red wire would go to the acc side of the ignition switch. Then, when you turn the car -on-, the radio works. Otherwise, when the car is off, the only power received by the stereo is on the orange wire and the only operating function is the clock. Only when the car is -on- does the radio/tape actually work.

bunch 1 : blue/black...bunch 1. not sure, possibly line in for an equalizer.

Bunch 2: most likely, this is left channel positive and negative (to speaker left)
most likely, this is right channel positive and negative (speaker right)

Without trying it, it's hard to say. Does the radio have a "fader" for
front-and-back speakers, or is it only a 2 channel output (left and right but no
front and back)???

Keep your posts here...someone can probably help ya.

5497. Measuring phase-noise with HP 8640B

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-25 00:00:00 UTC
From: jeffa@ix.netcom.com
Message-ID: <495ui8$t6@ixnews3.ix.netcom.com>
Source record: 109360

I was just skimming the Handbook and came across an interesting article discussing oscillator phase-noise, and a simple technique for measuring it by phase-locking an HP-8640B generator to the oscillator signal.

Unfortunately, it was more of a summary of the technique than a detailed descripton. I have an 8640B, but it's the militarized option 323 version, and so lacks several of the standard version's features. As anyone tried this technique? I have several questions about it and the "useability" of the option 323 version generator for this application.

Question 1: Although the 8640B has a "lock" feature that allows it to lock to it's internal reference, the option 323 lacks this feature. Is it needed for this application? I'd think not, since, in this application, the generator is being locked to the oscillator using an external phase detector (mixer) and low-pass filter, the output of which is applied to the external FM input. I can't see any reason why I'd simultaneously need to lock to the internal reference. However, there may be a good reason. As anyone tried this with the lock ON, and with it OFF? Any differences in measurement?

Question 2: I think the article mentioned that the filter was a 1 MHz low-pass. How many poles should it be? Is shape important, or can I get by with a simple topology (like, say, an RC lowpass)?

Question 3: Any harm in using the generator's external sync output (basically a square wave, rather than a nice sine) to drive the mixer? Again, I'd think not, but an experiment might be in order.

Does anyone know more about this technique? I've got all the equipment here (including an ancient HP 3591A Selective Voltmeter, which ought to give me some interesting plots on my equally old 7035B XY Plotter).

Also, is anyone familiar with the circuitry of the 8640B? I'd like to find out what the actual differences are - perhaps I can make a mod to give me the lock feature, if required. I've sketched out some ideas, but knowing what HP really did would help...

Thanks!

Hey, *until* you get your LCR meter or dip meter (Christmas is coming!), I've found that about 10pf per plate pair is a reasonable figure for many caps. Caps with big plates and small spacing, like BC receiver tuning caps, are more like 30pf per plate pair.

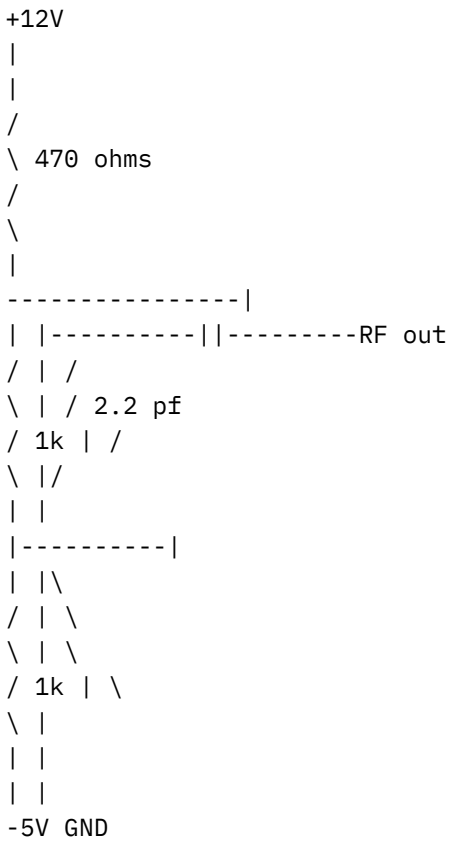
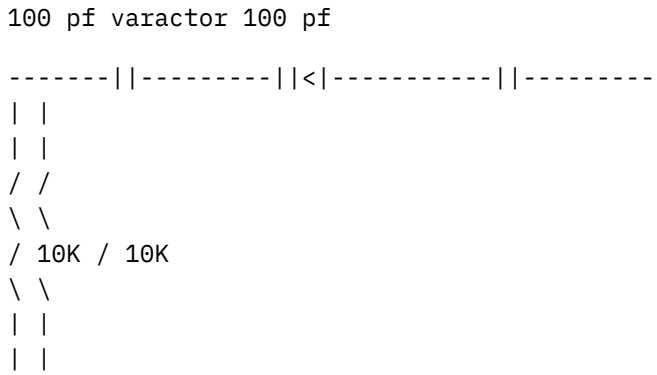
1. Get a microwave transistor, such as BFR90
2. Connect the following bias circuit:



3. Connect the following from collector to base:



If the frequency of oscillation is too low, shorten the leads on the tuning network. If it is too high, lengthen them. The tuning diode resonates with stray inductance. It is fairly easy to get this to tune from say 1 to 2 GHz.

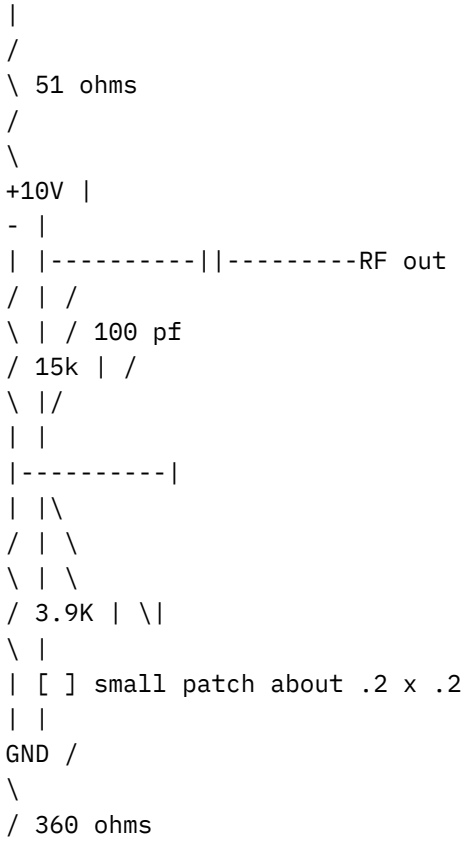
You can also try this: using a MRF901 or similar transistor:



\
|
GND

Connect the center of an open piece of semirigid coax of 50 or 75 ohm impedance to the base of the transistor. Make it
about 150 degrees long and ground the shield. Trim the lenght of the coax to oscillate at the desired frequency. To vary the
frequency apply the vco voltage to the base of the transistor using a 20K resistor. This voltage can be a few volts. There
is no varicap required since the s-parameters of the transistor change with base bias. I have used this simple circuit to
transmit FM video using a simple pre-emphasis network in front of it.

: Other than name (Amp Supply Co.) no other mfgr identification. Can you
: help me with a source to purchase a new plate choke and tubes ?

Remove the choke. Unwind the old wire and save it. Buy some new magnet wire of the same gauge at Radio Shack. Cut a piece of new wire the same length as the original piece. Wind the new wire back on to the original form. Re-install the choke. That's it.

5517. The N4TMI Desoldering Contest

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-26 00:00:00 UTC
From: mcovingt@ai.uga.edu
Message-ID: <49abeq$p4b@hobbes.cc.uga.edu>
Source record: 109430

THE N4TMI DESOLDERING CONTEST

This evening (November 23, 1995), I decided to hold a fair competition between all the different desoldering techniques available to me. Here are the results.

I would appreciate comments on these notes from anyone more experienced.
^^

The goal in each case was to remove some ICs, undamaged, from a double-sided circuit board (part of an IBM PC AT); this is the most difficult desoldering task that I routinely face. Single-sided boards are _much_ easier to deal with.

Unless otherwise noted, the heat source was a 40-watt Weller temperature-controlled iron set to 750 F, and in each case I tried the technique quite a few times before drawing conclusions.

GENERAL PRECAUTIONS AND TECHNIQUES:

- All of these techniques work better when I wear magnifying goggles (2x). That makes it much easier to see the condition of the surface of the solder.

- Desoldering takes time. All the techniques work better if each joint is heated 5 to 10 seconds beyond the point at which it appears to melt. That helps ensure the solder is melted all the way through the double-sided board.

- If a joint fails to desolder properly, the thing to do is add more solder and try again. It is almost impossible to remove the remaining solder from a half-desoldered joint.

TECHNIQUES AND RESULTS:

(1) HOT AIR GUN

Overall performance: VERY GOOD. Even 40-pin ICs were removed easily. No damage to the board occurred (not even scorching of labels).

Technique: Use a 1200-watt Black and Decker hot-air gun, with 1/2" diameter tip, positioned 1/2" from the solder side of the board, to heat all the pins of the IC for about 30 seconds. Meanwhile, pull on the IC from the component side with pliers or an IC extractor. When the solder melts, it can be pulled free. Some force is needed because the pins of the IC have been bent to hold the IC in place.

I just thought of this technique today and was delighted to see it work so well. A similar technique with a propane torch is sometimes suggested, but it is more likely to scorch the board.

With this technique, the IC gets rather hot, but probably no hotter than during initial wave soldering of the PC board. The IC case stays below 200 F as judged by the water-drop test.

Precaution: Droplets of solder may be blown through the holes and land in unexpected positions on the component side.

(2) EDSYN SOLDAPULLT

Overall performance: ADEQUATE. Fine for small components (up to 8 pins); tedious for larger ones.

Precautions:
(a) Internal cleaning and lubrication of the Soldapullt is very important.
(b) For best results, melt the solder fully, then keep it melted by applying the tip of the iron at one edge while putting the tip of the Soldapullt on the middle of it.
(c) After removing the solder, free up the IC pin by moving it to the middle of the hole either with pliers or with the tip of the soldering iron. THIS STEP IS CRUCIAL for the ICs to come out undamaged.
(d) A big Soldapullt performs better than a small one.

(3) DESOLDERING IRON WITH RUBBER BULB (Weller DS-40)

Overall performance: POOR. ICs could be removed with difficulty. With smaller components or single-sided boards, it would be adequate.

Special precautions:
(a) Inadequate heat transfer is the biggest problem; often a joint simply doesn't melt.
(b) To ensure good heat transfer, the tip must be clean, well tinned, and the same size as the solder pad on the PC board (neither much bigger nor much smaller). Best results are achieved when, at the moment of initial contact, there is a droplet of solder spanning the hole in the tip.
(c) Before sucking away the solder, use the tip to wiggle the IC pin back and forth, leaving it in the middle of the hole rather than at the edge.

Some improvement results from attaching the Soldapullt in place of the rubber bulb.

(4) COPPER BRAID (Chemtronics Chem-Wik Lite)

Overall performance: INADEQUATE for this job; I could not remove all the solder from a hole in THIS board using this material. It is of course quite adequate for single-sided boards, and very helpful for cleaning up solder from inopportune places.

(5) SPECIAL TIP TO HEAT SEVERAL PINS SIMULTANEOUSLY

I have not tried these special Ungar tips, which have been a standard item ever since ICs appeared on the scene. I am thinking of making a homemade steel or copper tip just to check the results.

An obvious problem is that a different tip is needed for each size of IC (although one could probably get away with using the 16-pin tip on 14-pin PCs).

Comments welcome!

I have used copper braid quite successfully when I am interested in salvaging an IC. However, the cleanliness of the solder is a BIG factor in how successful the technique is. Whenever I am using copper braid, I will always apply additional flux to both the braid and the joint. The solder seems to suck up into the braid leaving a clean hold and the part ready to remove. Couple of caveats though. 1) The pins usually need to be broken free from the side of the hole since a small amount of solder remains. I tend to do that with my fingernail since using the iron sometimes leaves the problem of the pins resticking to the hole. 2) Multilayer boards where the pin is connected to an internal ground plane are sometimes rather difficult to removed the solder. Thermal pads in the original board design help out a *LOT* to reduce this problem.

How well does the MGF1402 work at 150MHz in general? If it is
stable, I'd guess the noise figure is low enough that you need
not worry about it :-).

JJ>esteemed colleague Mr. Coffman... I've never INTENTIONALLY used
JJ>one for an oscillator but have lots of experience trying to
JJ>tame mmic circuits acting as oscillators but designed as amps
Hi gang,
Yes I agree the term "unconditionally stable" is frequently misunderstood. It does *not* refer in any way to the use of the device as an oscillator, nor to it's anticipated stability in a given physical implementation. It *does* indicate that in a *properly executed* state, the device in question will not be more or less likely to oscillate with a 1:1 or some other, higher VSWR on it's input. Also, the output may be terminated in resistive, reactive, open, or shorted loads, and it will be no less (or more) *likely* to oscillate.
All of this assumes that you have built the circuit up on an RF worthy platform, have taken precautions to keep input away from output, etc. In other words all the normal RF design rules for a non-oscillating ckt have been followed. This is what is meant by *properly executed* above. This may seem to be a trivial spec to those that have carefully built amp ckts, only to have them oscillate, but try building one with a device which, even with *perfect* layout, must be terminated in the proper R+/- j on both the input or the output or it will oscillate! This by the way is called a conditionally stable device.

> Any differences in measurement?

I have an 8640/323 also. It omits the "lock" feature probably because
the military correctly realized that it was of dubious value and was
not "soldier" proof, being that it will remain in lock for about 2
minutes at a time, typically. Also, it is a frequency lock loop using
the built in frequency counter, not a true synthesizer. Hence don't
even ask about phase noise clean up, there ain't none. You're better
off without it. Who knows how it would interact with the external
FM port?

>
> Question 2: I think the article mentioned that the filter
> was a 1 MHz low-pass. How many poles should it be? Is
> shape important, or can I get by with a simple topology
> (like, say, an RC lowpass)?

It must be either a 1 pole, or a 2 pole/1 zero filter for loop
stability. This is basic phase locked loop theory.

> Question 3: Any harm in using the generator's external sync
> output (basically a square wave, rather than a nice sine) to
> drive the mixer? Again, I'd think not, but an experiment

I would get it working with the sine wave first.

>Does anyone know more about this technique? I've got all the equipment
>here (including an ancient HP 3591A Selective Voltmeter, which ought to
>give me some interesting plots on my equally old 7035B XY Plotter).

Measuring phase noise in general is non trivial and requires a lot
of knowledge of both math and hardware gotchas. You can get some
HP ap notes from your local sales office that explain phase noise
measurements. Definitely read these first.

>Also, is anyone familiar with the circuitry of the 8640B? I'd like to
>find out what the actual differences are - perhaps I can make a mod to
>give me the lock feature, if required. I've sketched out some ideas,
>but knowing what HP really did would help...

They simply compare the counter reading to a preset register and steer
the oscillator accordingly. Wayne Ryder published a receiver article
in Ham Radio about 15 years ago that used a locked VCO with the circuitry
stolen from the 8640B. Again, you don't want to use the lock feature.

>
>Thanks!
>
>- Jeff, WA6AHL

The 8640 has great phase noise far from the carrier (20 kHz.) but
for close in phase noise measurements, you want to use a crystal
oscillator as the reference. Again, I haven't read the Handbook
article, so I don't know where they were coming from.

5530. Standard Broadcast Antennae

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-27 00:00:00 UTC
From: FJEX69A@prodigy.com
Message-ID: <49bcls$mrg@usenetz1.news.prodigy.com>
Source record: 109440

Does anyone have any suggestions on building an antenna for the Standard Broadcast band (you know- AM radio) in the form of a small coil or loop? I would like to create a deep null so that I can receive WLAC, a cleared-channel station over the noise created by a local station 20 kHz away.

Considerations-

1) The Zo of the antenna input on my receiver is unknown, as no person at the local representative of the Nippon Gakki Co. Ltd. was able to provide this.

2) Should the turn be concentric or a spiral to be cut by the most lines of force from the M-field of the signal?

3) Is noise from local interference generators (like power lines, HID lamps, SCR devices) mostly static or magnetic?

Thanks for any comments.

Your technique with the hot-air gun was interesting, but anytime you pull on the IC while the solder is molten, you risk lifting the pad off the board. A better way, although more expensive, is to use one of the power vacuum devices made by Hakko, Pace and others. They heat the board while applying a vacuum which you control with a pushbutton. You can do a very thorough job of removing the solder from the hole before exerting any pull on the part. They cost in the several hundred buck range though, more than most hobbyists would want to spend. They are what the professionals use, and if you have access to one, that's the way to go.

Hi Rich,

Amp used all types of chokes in the 1000. Some were surplus and some were homemade. You do not need all the inductance the surplus chokes had, they were huge and impossible to re-wind as built.

Actually if you close wind either form with #20 enamel you will do ok. The only rub is the choke may have a series resonace that causes it to burn up on some bands. I can suggest a method to test for and cure that problem if you like or need.

Good luck on the tubes! The price is outta sight, and the amp will gobble them up if you do anything wrong when tuning...even for a few seconds!

: How well does the MGF1402 work at 150MHz in general? If it is
: stable, I'd guess the noise figure is low enough that you need
: not worry about it :-).

Well, if I just look at the "appendices" of the ARRL Handbook, there are plenty of Preamps build with this FET. That would probably mean it is stable. NF is given as 0.4 dB. I just wonder if it can be lowered, I'd maybe like to use this rig for EME (at least in reception)

But again, lacking S params, I can't figure out the area of stability. The input stages given in the Handbook are of little use, I simply can't convert from those b***y american unities into metric.

BTW, whereis Sun's hardware lab ? I should work there for three/four months quite soon.

Good afternoon,

Working on a project for a class, and had some specific questions...

1) I am working on a 900 Mhz design, any special considerations you
would recommend ?

2) What is the effect of the material used on a cavity/tuning rod/etc. ?

3) What determines the diameter of the cavity ?

4) Should the cavity be a 1/4 wavelength ? If it were 3/4 wavelengths,
how would that affect performance ?

5) What is the purpose of the "coupling loops(s)" ? What considerations
are needed to develop the geometry ?

6) Can a duplexer be achieved with a tuning shaft that is simply a screw
into a cylindrical cavity ? What is the effect of the cylinder in a
cylinder design ?

7) Are the interconnecting cables 1/4 wavelength ? What is the significance
of the interconnecting cables ?

8) What is the circuit element model of a cavity ?

9) How can I determine insertion loss and isolation of a design ?

10) What would you recommend about shunt capacitors and inductors ?

11) How do you determine the Q of the cavity circuit(s) ?

>solder from a half-desoldered joint.

As one who's been known to pick up TV sets left at the curb on trash day for purposes of scrounging the parts inside, I feel qualified to answer.

In the above case, another trick is to turn the board over and try again from that side. Often the half-desoldered joints are caused by a big ground plane or some such sinking all the heat from the pin on the opposite side.

BTW, my results over the years (some of it done for a living) exactly match yours. Heat gun is #1 for rapid desoldering of multiple joints. If the parts on the particular board didn't have every little lead bent over to hold them in, you could melt large areas and just watch the parts fall out.

#2 is solder suckers of various sorts. These clear the holes of solid solder so you can pop the pins loose by wiggling a little. The pins are indeed often still bonded slightly. Rather tedious, but it works.

Solder wick is mostly for helping clean up after #2. I've never managed to get it to properly desolder plated-trough holes very well.

Adding a bit of solder does help sometimes. I've come to the conclusion that this has more to do with the rosin cleaning out the joint than with the actual solder. Seems like both the iron and the joint get a bit oxidized and won't transfer heat very well.

If you want to save the board, DON'T apply any kind of force to the part you're extracting. The plated-through holes pop out very easily when hot. Let the iron do it's job and gently tug the leads free. If they don't loosen up, something else is holding them or the solder isn't melting.

Happy scrounging!

-Tom R. N1OOQ randolph@est.enet.dec.com

Ill jump in and add my $.02

I repair 9 layer boards that have 120 pin piggyback modules on machined copper pins soldered into plated through holes, attached to large power & ground planes in both the motherboard and the piggyback board. A desoldering nightmare!

We need to remove defective modules without damaging the motherboard and leave the holes open for the new part.

It depends on what you are wanting to save, the pcb or the chips.

DONT USE A TORCH!!!, it will burn your PCB, and oxidize your chip pins and make them hard to solder. The high heat can also "Thermal shock" your chips too! Dont know thermal shock, drink some hot coffee, now take a bite of ice cream, your teeth shattering is from thermal shock. Heat does the same to silicon.

Hot air is wonderful for removing or preheating boards/chips for solder suction removal. To just save the chips heat the pcb from the back and yank, but you will leave solder in the holes that will be nearly impossible to get out.

To keep the PCB in good shape, use a combination method, flux the pins of the chip to be removed, both top & bottom, stand or prop the board up on its side so that the solder is travelling horizontally, gravity makes a difference. You can then hot air from top side while using desoldering iron (suction, squeeze bulb, or pump) to suck the solder from the pin/hole from the bottom side. Dont run the air hot enough to melt the soler though, or you may have bridges develop, or have other components skew, let the iron make the final melt. Desolder the pins in a row, 1,2,3,4... dont jump from side to side, 1,20,2,19,3,17... When you desolder a pin, you will also be warming up the pin next to it, work quickly, dont wait for it to cool inbetween pin desolderings. So desolder while the pin is hot. Its easier to desolder a pin thats 400deg F rather than a pin thats 70deg.

We use Hakko 850 hot air stations and Hakko 470 powered suction irons. We tried weller, pace, denon, ok industrys, ungar, APE, Dragon. The hakko passed the "Ed test".

>What about stripline instead of coax? At least simplier to construct...

A stripline is not shielded, while semirigid is. I think a stripline will work (Glenn explained that to me recently), but he used multilayer to shield it. I'd take semirigid over the pain of making stripline every day. Can you imagine an oscillator that doesn't detune (much) if you touch it, or waive in the neighbourhood?

Another reason for me liking semirigid here is that I plan to use this for a transmitter, i.e. add a few amplifiers behind. As an oscillator is a very sensitive amp (it oscillates, right?) this shielding will be helpful.

Try it, just for the heck of it. I was amazed; I hope you will be too (yes, free-running FM ATV is trivial)

>hmm. Think I have a bunch of BFR540 available cheap. What about them?
I don't know that type. Pro-electron suggests 2 digits behind BFR; is that type number correct?

Have fun hacking,

I do quite a bit of work with FM ATV here. While I have no
specifics on diversity video reception, I do know that the
commercial broadcasters use digital frame storage devices
which hold the last frame or implement individual line
replacement during signal dropouts from portable cameras
and aircraft etc. Because these are out door operations,
diversity and multipath may not be as big an issue with them.
I think you may be getting into a new area of research.
I have heard of others using FMTV indoors and have heard similar
complaints.

Good Luck,

Steve Muther WF6R

5554. RF choke color codes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-27 00:00:00 UTC
From: "Colin Schmutter"
Message-ID: <49dev0$i2e@chopin.bcit.bc.ca>
Source record: 109464

I am a bit unclear as to how the color coding scheme applies to small RF chokes. The type of choke I am refering to look like small resistors and have colored bands around them.

I can see that the first and second band refers to a digit value as in a resistor but the multiplier band confuses me.

For example what value would a choke with the colors brown black and orange represent?

Any help would be appreciated.

cschmutter@bcit.bc.ca

The problem I see with that is when people work together at the same location a "pecking order" is established. Portions of the review process are severly hampered or destroyed by the "pecking order", although it is better than one person.

>Some stuff does have a short shelf life--we do know that

>
>Looks like we need to hire an expert on managing volunteer labor.
>How do you get them to give the volunteer work you hand them top
>priority? People change jobs and they seemingly vanish...

The biggest complaint I hear from technical advisors and their assistants is they are kept out of the loop. People actually want to help, and there are so many of them out there I can't imagine not being able to find several dozen respondents.

>Its also an interesting problem to decide which expert/experts
>are right. I was surprised to find out that the K2RIW 432 MHz
>parallel4CX250 amp was actually rejected by Ham Radio.

That's true, but I was equally surprised to see the Handbook include a steel wool balun, a forward acting speech processor, a linear amp that connects the blower and filament transformer primary wiring to the chassis, and so on. Look at the inability to resolve the Bruene/Maxwell disagreement when a simple lab test would provide the truth!

Perhaps both review systems have the same problem, a few people that work together make decisions without considering or requesting outside independent input.

Actually I'm not sure they are photoflash. They are CDE type LPC111-1 40
mf 3 kV. I also use GE 33 mf 4 kV. One 3CX3000 amp here has been running
since 1978 with CDE's at 2800 volts per cap in a cap input full wave
supply!

I thought you would have a more painful response to my 50 Hz dig, but I
guess not. I'll try again later. ;-)

The NE604 is a completely different IC than NE602. They have not even the same amount of pins. (16 vs 8) Substitute the NE602 with an NE612 which is a pin for pin replacement but has a slightly better perfomance.

I use a static hot air source for much of my work. Let me make a few
suggestions. First, you want a *static* hot air source. That has several
advantages, notably it won't blow solder (or parts) everywhere, and it's
easier to control exactly where the heat will go. I normally use either a
Weller Pyropen or a Bernz-O-Matic torch, either fitted with a proper
heat shroud and baffle. (Weller sells some for their Pyropen, and you
can make others from simple sheetmetal. The bigger torch is most useful
for huge multilegged parts.)

Second, for thru-hole boards, deal with any cinched pins first. Just
heat the pin with an ordinary fine point iron and use your "Greenie"
(the ubiquitous Xcelite R3322 every tech *always* has in his shirt
pocket) to pry the pin back straight.

Now if you are trying to *repair* the board, build up a small clay
dam around the part to be removed. Just use a 1/8th inch to 1/4 inch
roll of modeling clay formed around the pins of the part to be removed

to keep the hot air from spreading to other component leads. If you're just salvaging chips, you can skip this step.

With the board held in your hand, *quickly* heat the pins with the hot air source (with either torch recomended this should take no more than a couple seconds, with the big torch held further away to control the heat flux). Now rap the board sharply against the bench and the part should fall out. Alternately, you can pry it off from the component side with the Greenie or with a chip puller, but if you do you run the risk of damaging the board, or the part. It's better if you can make it fall out.

This technique works even better with SMD parts since they aren't bound to the board with anything but solder. (Some are, however, with a dab of adhesive between the board and the part body, for those, apply the Greenie to pop the part off the board. Just make sure the solder is molten when you do this or traces may come up.)

I can't emphasize enough that you need to work *quickly*. Otherwise you can overheat the part or the adhesive holding the trace to the board.

Nothing can beat the static hot air source for *installing* a SMD part either. Just put a dab of solder paste on each *clean* pad, set the part in place (with the clay dam installed to avoid heating other parts' joints), and give it a shot of static hot air. Surface tension of the molten solder will pull the chip into perfect alignment. As soon as it does, remove the hot air source and let cool before disturbing. (This obviously is a case where the hot air source has to be static, otherwise it would blow the part out of alignment.)

Now let me talk about another *repair* technique with thru-hole parts. Often you know a chip is bad, and need to remove it to install a replacement part. With a multilegged DIP, this can be a tedious process fraught with danger to the board. So just snip the part off the board from the component side with a pair of fine dikes. Now you can either remove each pin individually with a fine tipped iron and a pair of needlenose pliers, or just leave them there and solder the replacement part to the pins left from the old part. This latter method is ugly, but it's fast and it offers less trauma to the board, especially if it is a multilayer board.

Gary

The ARRL has a collection of volunteer Technical Advisors, experts in various fields. In many cases, as an incoming article is in the queue for review, we elect to take the extra time to send it off to one or more of these volunteers, in addition to the in-house review by the editors and Zack here in the Lab. In most cases, the TAs are able to review the article fairly quickly and advise us before we publish. For many types of articles, we won't accept the article until it has received review by an expert we trust. However, volunteers are *volunteers*, and in my experience, sooner or later every volunteer has a busy time in his or her life and cannot drop what they are doing and tend to an ARRL matter for us.

However, from personal experience, I have also found that the experts do not always tend to the details. Even some of the authors have not noticed that U2B appears on the schematic twice. When I did my first technical review on a QST article, I almost glossed over the schematic, reading the text for the overview, looking for the gross technical misrepresentation. I assumed that the details had to be okay, and they wanted my expertise for the big picture. I soon figured out that it is the details that were wrong, not the big picture. Once I spent the time to carefully read each line in the text, and make sure that if it said

"adjust R2" that R2 wasn't a fixed resistor, I was catching some of the potential errors. Fortunately, it doesn't take an expert to locate those types of problems, it takes someone with a sharp eye and the patience to spend up to a full day on a large construction project poring over and verifying the details. We are not in a position to demand this of outside volunteers, but we can pay staff to do it.

As Zack pointed out earlier, we are committed to eliminating all errors in QST articles. We use a good combination of outside people and paid technical staff to do just that. We will never succeed 100%, but I don't want to see any errors that could be caught by careful review of the details. The recent case in question involved an article that had somehow dropped into a crack, lost perhaps in some shuffling of staff responsibilities. Zack and I are very concerned about what may have gone awry and how to change the process so it doesn't happen again. We are working with Steve Ford, our Managing Editor, to ensure that the articles receive the external and internal review for technical accuracy. Zack has worked very hard to improve the quality of ARRL publications, identifying and catching many potential errors before they get to print.

Source record: 109473

A couple of weeks ago a customer of ours addressed me with
a problem that is closely related to ATV.

They are using 1,4 GHz low-power FM TV transmitters indoors
to transmit picture from a moving vehicle to the remote
control site. Needless to say that the picture quality is
plagued with multipath drops even when the vehicle is close
to the receiver. I suggested that they should try several
receivers with diversity combiners and the result was that
they came back asking for more information...;-)

Has anybody tried diversity reception with FM ATV? And if you
have, what have you used as the diversity criteria? Are there
any articles about the subject and combiners?

Also pointers to commercial video diversity combiners and manu-
facturers would be greatly appreciated.

73 de Benjamin OH3BK

PS. The FM TV equipment they use now was made by Microwave
Modules. I have a faint idea that they have gone out of business,
are there any successors? Sinclabs?

Peter,

The technique is on page 14.12 of the '95 edition of the "Radio Amateur's Handbook" (and can probably be found in other Handbooks). It is also discussed in the two-part series entitled "Phase Noise and its Effects on Amateur Communications", published in the March and April, '88 issues of "QST".

Good point. Interestingly, the Handbook stated that the 8640B "has a much cleaner spectral output than most transmitters", and so would be adequate in this application. I wonder if the ARRL's Lab has compared the results of the 8640B method with those from commercially available phase-noise measurement systems? How much worse is this technique? Its virtue is that, if you already have an 8640B, it's very simple.

If only I could afford an '8662...

Rick wrote:

>FM port?

HP *claims* that there is little interaction with the FM port ("...assures no degradation in noise from the unlocked mode"). But who knows?

Rick, thanks for pointing me towards Wayne Ryder's article. I dug it up last night -- interesting! I don't know how much of the 8640B's counter section he scavenged, but I was surprised to see that the counter stops counting in lock mode. I can understand Wayne doing this for simplicity and parts count sake, but I assumed HP would keep the counter functional - otherwise, how would you see the frequency change if you're in "x100" expanded mode, and you're tweaking the time base +/- 20 ppm? (This also means, I think, that the "tweakable" time base cannot be the counter's time base -- otherwise, you'd never see the frequency change as you tweak it).

I was pleasantly surprised to see how similar HP's technique was to the one that I'd blocked out Sunday afternoon (although I planned to keep the counter running -- hard not to do without making MAJOR mods, although it does mean more parts).

(As a side note - to those who are complaining about QST's technical error's, take a look at the counter schematic in this article!)

A final question - why is this not a "true" synthesizer? I don't know much about synthesizers, but it looks to me like a typical synthesizer schematic: VCO divided by M, reference divided by N, both go to a phase detector (cleverly combined with the VCO counter's control logic), whose output is then filtered and fed back to the VCO. How is this different from a real synthesizer?

Thanks for the help.

Source record: 109231

Jeff,

I haven't read the article either but I thought I might drop some
numbers in case they might be helpful. Typically, the 8662 which
is mentioned as a "golden standard" has SSB phase noise of

Offset from .01-120M 120-160M 160-320M
Carrier dBc dBC dBc

10 Hz -113 -120 -113
100 Hz -130 -132 -126
1 KHz -134 -138 -133
10 KHz -137 -148 -143
100 KHz -134 -146 -142

While these are generally good numbers, I have found that except in
the decade centered on about 100 Hz offset, a good vhf crystal
oscillator locked to a decent 10 MHz reference with a low bw loop can be
even better. Overtone crystal noise generally falls at -30 dB/ decade and
can be 'out of sight' at fairly low offsets. If a good reference can
clean it up below that corner, the result is good indeed.

I show an example of this in a series I did several years ago in Ham
Radio Magazine, Feb/Jun/Oct 1988. I don't claim that oscillator circuit
is the quietest that can be done, I've done better since, but I think
something along that line can be made to be very quiet and that an
inexpensive circuit like this can rival or beat the above numbers at
most offsets. The article shows the results of multiplying and locking
this oscillator to microwave. Of course, a crystal oscillator phase
noise reference isn't going to have the flexibility of a synthesizer but
it may serve to help develop a low noise generator or transmitter.

In addition to the raw oscillator performance, really good design
requires attention to all the buffers, dividers, phase comparators
involved and there can be a lot of layers of onion to peel in order to
get the very best performance.

I hope the above is useful.

Real AC motors generally generate very little interference. The motors
in vacuum cleaners and drills are *universal* motors, IE they don't care
if you feed them AC or DC, and have nasty brushes which arc like mad.
The only solution to this sort of noise problem is to *suppress it at
the source*. All the usual things can be applied, shunt capacitors,
series inductors, shielding, etc. The best solution, of course, is to
replace the motors with brushless true AC motors.

This filter may not be needed. It was added to avoid
relying on the spectrum analyzer to ignore the high
frequency products coming out of the spectrum analyzer.

>
>I simply don't have any kind of info on this GaAsFET.

DJ9BV published S parameter data for the MGF 1302 in the No. 2
1993 DUBUS. The 1302 is a 1402 in a less expensive package--it
shouldn't make much of a difference at 2 meters. You might be
able to estimate the noise parameters from the information in
his 2 meter preamp article published the previous issue.

The French representative to contact for back issues is
Patrick Magnin, F6HYE. Rus, N7ART is the person to contact
in the USA.

5575. N4TMI on Desoldering: MORE DATA

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-28 00:00:00 UTC
From: mcovingt@ai.uga.edu
Message-ID: <49dstk$ieg@hobbes.cc.uga.edu>
Source record: 109238
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.repair

Thanks to all who responded to "The N4TMI Desoldering Contest" with advice and suggestions.

I made another trial with copper braid ("Chem-Wick Lite") this evening and found that I had been using it wrong. Tonight's notes:

(1) For best performance, the braid should *not* be spread out; it should remain narrow, just as it comes off the roll. That way, you get more wicking action.

(2) There's a lot of solder in each hole of a PC AT board. Each joint will need to be melted into copper braid about 3 times, using a fresh place on the braid each time.

Overall performance: VERY GOOD albeit slow.

5578. $29 PIC Programmer pricing ends 12/31/95!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-28 00:00:00 UTC
From: itutec@aol.com
Message-ID: <49gfaf$1jb@newsbf02.news.aol.com>
Source record: 109241

Our special introductory pricing on our PIC-1 programmer and PIC-n-GO package will END December 31st OF THIS YEAR! Place your order now to receive your own PIC programmer at this incredible price before the holidays(an excellent gift idea for the electronic hobbyist!). Our PIC-1 programmer has been making news in Electronics Now, Popular Electronics, MicroComputer Journal, Electronic Products and was featured in Nuts and Volts Magazine. See our Web page for more information. Call us today to place your VISA/MasterCard order!

Remember, we include EVERYTHING you need, CABLES and POWER SUPPLIES!

ITU Technologies is proud to introduce the ITU PIC Programmer Model PIC-1, the first truly low-cost and versatile programmer for the Microchip Family of PIC microcontrollers. This programmer is designed for programming Microchip's popular PIC16C6x/7x/8x family of microcontrollers. The programmer is approximately 3.3" x 3.7" in size and features a built-in 18 pin DIP socket and an expansion header. The expansion header is provided for programming adapters and in-system programming of EEPROM-based PICs. A variety of adapters are also available to support 28/40 pin DIP PICs and other packaging forms. The PIC-1 programmer comes complete with an interfacing cable to connect to your PC parallel port, programming software, and power supply. The included power supply is for US use only, foreign customers must provide their own converter/power supply.

The programming software included is designed to program all of the supported PICs mentioned above. Software updates will be available electronically free of charge. The software allows programming of the PICs program memory, setting of configuration fuses, program verification and the ability to read PIC memory to a file. The software also allows data memory programming, reading of data memory, and bulk erase of EEPROM-based PICs. The software is DOS-based and is Windows95 compatible.

An UNREGISTERED shareware version of Don Lekei's Macro+ Assembler for Microchip PIC Microcontrollers (ASPIC) is included with each programmer for your evaluation.

SPECIAL INTRODUCTORY PRICING FOR INTERNET CUSTOMERS
THIS PRICING ENDS December 31st, 1995, HURRY!

ITU PIC Programmer (Model PIC-1) KIT $29
This kit includes:

* an easy to follow instruction manual for building your programmer
* a high quality printed circuit board with silkscreen
* all components needed to build the programmer
* PIC Programming Software for IBM PC AT-compatible Computers
* a cable to connect the programmer to a PC's parallel port
* a power supply for the programmer (for US use)
* a User's manual introducing the PIC-1 programmer and software

ITU PIC Programmer (Model PIC-1) Assembled/Tested $49
As above, but assembled and tested.

ZIF Upgrade Additional $11
* ZIF Socket Upgrade for PIC-1 programmer

40/28 PIN Adapter Assembled/Tested $25
* an adapter with ZIF socket for programming 40 and 28 pin DIP PICs

---

ALSO AVAILABLE PIC-N-GO PACKAGES:

PIC-N-GO packages are designed for the microcontroller novice. They include the ITU PIC Programmer Model PIC-1, as above, plus a PIC16C84-04/P microcontroller. This EEPROM-based microcontroller is ideal for the novice and the PIC-N-GO packages are the most attractive programmers available for the beginner. You can program and erase the PIC16C84 many times without the use of an EPROM eraser, making it the best choice for those starting out with microcontrollers. These packages are great for students and hobbyists looking to acquaint themselves with microcontrollers.

PIC-N-GO KIT only $39
* includes PIC-1 programmer kit and PIC16C84-04/P microcontroller (w/ data sheet)

PIC-N-GO Assembled/Tested only $59
* includes assembled and tested PIC-1 programmer and PIC16C84-04/P (w/ data sheet)

EXTRA PIC16C84-04/P Chips (with purchase of package) $7

THIS SPECIAL PRICING WILL END 12/31/95, SO ORDER TODAY! Don't miss this special opportunity.

Quantity discounts are available, making these packages the perfect choice for schools and clubs wishing to teach introductory microcontroller usage.

All products include a 30-day money back guarantee and a 90-day warranty. Due to the nature of kit building, all kits must be returned unassembled to qualify for a full refund.

Please add $5 for shipping/handling inside North America. An additional $5 service charge is required on COD orders.

You may place your VISA/MasterCard or COD order via phone. Our telephone number is (513) 574-7523. You can also mail in your check or money order to :
ITU Technologies
3477 Westport Ct.
Cincinnati, OH 45248-3026

Please feel free to e-mail us with your questions or COD orders at sales@itutech.com or ITUTec@aol.com.

See our Web page for a photo of the PIC-1 programmer and more details!

[snip]

Ricks post is most informative on this topic. The operative word
in the handbook article is "crude" phase-locked loop. If the
oscillator under test is any good, what they are measuring is the
performance of the '8640.

If they had an '8662, it would be a different story.

I know this is in the wrong group, sorta, but if anybody could point me in the right direction.

I am creating a 2 station internal phone system. I have a 12-volt bias on the line. Everything works fine.

ONE CATCH: When phone A is picked up, I want phone B to ring. When phone B is picked up, I want phone A to ring. Not continuosly, but 1 ring of 4 seconds (standard) would suffice. This should be automatic, i.e. no buttons to push, as I have a cordless phone as one of the ends.

I am looking for either a manufacturer or schematics.

Thanks

While this is certainly true, unfortunately, we haven't yet seen an
oscillator in amateur equipment that is better than 10 dB worse than our
HP8640s. If they ever do get better, we will have to switch over to
using a low-noise reference crystal oscillator we have handy, at least
until someone donates a better signal generator. :-) (It would be tax
deductible, if anyone is feeling generous!)

The only solution to this sort of noise problem is to *suppress it at
the source*. All the usual things can be applied, shunt capacitors,
series inductors, shielding, etc. The best solution, of course, is to
replace the motors with brushless true AC motors.

What if you used a full wave bridge (prior to the motor) in order to
supply it with D.C., and then , across the brushes, used a clamping diode?

Can anyone offer some information on the new Kenwood TS-870 that uses DSP at the IF frequency.

What's the IF frequency? Has it been reviewed in any of the magazines yet? Inpressions? Strong signal performance, etc.?

Sorry if this isn't the proper newsgroup but I expect more of the "how it works" types here.

John, WB3ESS

>phase locked loop is, and the resolution of your phase detector.

It entirely depends on how this 1PPS signal is derived. If there is software intervention in its generation then there is little or no hope that it is accurate. Most cheap GPS implementations have the entire loop in software. This means the 1PPS output will have VERY good long term stability; but, it will jitter quite a bit pulse to pulse. If the PLL for the Costas loops is implemented in hardware then it can generally give a much better 1PPS signal provided it drives all the mixer LOs.

>In the Hewlett-Packard GPS timing receiver we make at this division, we
>approach an accuracy of 1 part in 10^12 for 1 day averaging.

It was designed with this in mind, I am sure. It is also not a cheap instrument such as the Magellans you find at Fry's or other mass marketing shops.

>If you just want to check the accuracy of your counter, simply measure
>the period of the 1 PPS output with averaging turned on. You can adjust your
>counter's timebase until it reads exactly 1 second.

It'd also allow you to watch the jitter if you have good enough resolution. (It "COULD" be as high as tens of microseconds of jitter for pure software Costas Loops.)

>Yes, a fellow from here left and started a company to do that.
>Theoretically, it should be better.
>The jury is still out on the merits of that architecture.

I am sure it is. Such a receiver would likely be rather expensive.

As another point in the discussion do not look for a short term average to give you an oscillator that is more accurate than about 0.1ppm. (That is "roughly" the range of the dithering on the signals. You ain't gonna do any better than that on a second by second basis. Note - I say "roughly". I think the precise numbers are still quite classified. I do know I designed that stuff so I am not about to use it as a frequency standard reference without at least an hour's

averaging time.)

5598. 40-40 mods, notes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-29 00:00:00 UTC
From: tiemann@spot.Colorado.EDU
Message-ID: <49ijkm$8j8@peabody.Colorado.EDU>
Source record: 109261

(I know this is a bit late, but...)

I've built the 40-40 QRP 40 meter CW transeiver described in the Nov, 1994 QST, and I've made a few mods and measurements that may be of interest to readers of this group. The receive sensitivity has been increased, QSK is approached, the use of a different final amp is described, and the tuning range has been increased. Birdies present within the band serve as convenient frequency markers.

The receive sensitivity of the 40-40 as built was low: My IC-726 with a 6' whip could hear signals that the 40-40 with a full size dipole couldn't. Two mods cured this: increasing C31, and adding a preamp.

With the antenna connected directly to the RF gain pot, R3, sensitivity was better than with the antenna at the intended place (L6/C30), indicating that loss occured somewhere in the front end. Walking the antenna away from R3 identified C31 as the deafener. Replacing it with a 1000 pF ceramic (it was supposed to be 68 pF) made the thing hear about as well with the antenna connected to antenna port as at R3, indicating there were no more significant front-end losses. This increased coupling did not lead to significantly louder sidetone on transmit; it was still just as much too loud. Increasing the 4.7 megohm TX-audio-shunt resistor interconnecting the drain and source of FET Q1 to 22 meg fixed it.

However, it was still insensitive, so how about a preamp? W1FB's QRP notebook describes "the preamp that ICOM uses" in it's HF transceivers - and sure enough it's in my IC-726 schematic. (I used MPF102s.) It's two grounded-gate JFETs on opposite sides of coupling transformers, with the drains 22 ohms from the plus rail, and the sources 22 ohms from ground, and both resistors bypassed on the transistor side by .047 uF caps, and it went between C31 and R3. It made the 40-40 *just* able to hear atmoshperic noise. It's nice because it's transparent to RF when power isn't applied - you merely give it juice if you want gain. It draws 10 ma - a good candidate for a front panel switch.

I found the hang time for T-R turnaround too long. It's dictated by the 1M resistor and 0.1 uF cap at the gate of FET Q1. A 0.01 for C was fast but gave a loud pop on T-R turnaround; a 0.02 was ideal.

For the final amp I used a 2SC2075, "identical to an MRF476," in place of the called-for 2N3553. (The MRF476 is spec'd for 3 W output at 50 MHz.) With the '2075, my 40-40 maxes out at about 4.5 watts. In contrast to the text "Adjust R2 as needed for 1.5 W key-down power [...] More is *not* better - you'll coax a little more power out at the expense of efficiency!" I found increasing efficiency with greater power, up to 3W, though this probably has more to do with the transistor than with the

circuit. I calculated the efficiency by measuring the supply current to the radio, and measured the RF output by hooking it up to the *antenna* side of my MFJ-949D tuner (so as to make use of the expanded scale on the"reflected" power meter) and terminated the "transmitter" port on the tuner with 50 ohms. With 15 volts on the rail, here's what I got:

0.05 watts output 80 ma TX draw 1.2 W Input 4% eff.
0.5 W 160 ma 2.4 W 21%
1 W 215 ma 3.23 W 31%
2 W 290 ma 4.35 W 46%
3 W 365 ma 5.48 W 55%
4W 510 ma 7.65 W 52%

So with a 2SC2075, it looks like the highest eff. is at 3W, right at the spec of an MRF476. Note also that though it drops up top, it's still more efficient at 4 W out than at 1.5 W out.

Increasing C9 above 68 pF is mentioned as how to get more than 40 kHz of tuning range. I settled on 270 pF for C9, and a MV1162 varactor - 275 pF nominal - for a tuning range of just over 130 kHz. This much added capacitance required reducing C5-C7 to .002 each, with some small NP0 caps (68 and 12 pF in my case - YMMV) in parallel to put the bottom at 6997 kHz. This is enough spread that a ten-turn pot is called for as the freq. knob, but I'm exploring use of two single turn pots, a "coarse" and a "fine," to spare my precious ten-turn pot from permanent imprisonment.

As promised in the text, there is a HUGE birdie right at 7000 kHz - and it makes an excellent marker! The radio is usable within 2 kHz of this birdie, so it doesn't result in much loss of spectrum, and I chose the bottom of the tuning range as 6997 to be sure I could tune across it. In addition, I found two other birdies, a weak one at 7077 kHz, and a strong one at 7117 kHz, and these too were suitable markers, also being unobtrusive and stable. (I wouldn't feel so kindly toward them if there were another means for frequency calibration!)

Next I'll make some KK7B direct - conversion transceivers... I suspect they will make an interesting comparison to the 40-40, at least on RX!

As the guy who brought up HP's 8662, I will agree with Glenn, after all
he works for them<g> The point I was making though is, the 8662 has the
ability to be used over a wide frequency range and has locking capability,
which Glenn's crystal standard does not.
So it the application under discussion, it is pretty much the "golden standard"
and is used as such in many HP phase noise test sets.

Hans,

Check the Oct 3. 94 issue of Electronic Design, I co-authored a design idea titled "Varactorless HF Modulator". This idea is based on using the base charging capacitance of a bipolar transistor to implement a voltage controlled (actually it's current controlled) capacitance. The structure of this oscillator is similar to Pieter Ibelings described above.

Hope this helps,

Mike Wyatt

>Mike, KK6GM

That's why a small form diameter single layer choke is best. The voltage from turn to turn is minimal.

Series resonance is avoided by: 1.) Using minimum inductance for the application (a few to several times the operating plate resistance) 2.) Space winding or removing turns in the troublesome areas

Winding a good choke is best done using Edisonian methods, cut and try. Series resonance should always be measured with the choke in the operating position and connected at the bottom, but the tank shorted out and the top of the choke floating from the amplifier circuitry.

A grid dip meter can be used by shorting the top of the winding to the bottom, dips indicate trouble.

A small light bulb (or current meter) can be used connected from the top of the choke (no short to bottom now) to the center pin of T connecter between a dummy load and the rig. The rig is moved up through it's range and frequencys where the bulb glows brightly indicate series resonance.

A swept impedance display can be used by the well endowed.

If a series resonance is found, a screwdriver blade can be moved along the winding. The resonance will suddenly move when the hot spot is "touched". Removing turns at that point in the winding will move the series resonance the greatest amount with the least overall inductance change.

Keep in mind that it is really important to characterize
the noise-floor of *your* system. We do this by comparing
our two HP 8640s against each other or by looking at a known
clean oscillator.

If you look at the specs for the 8640, they aren't that
great, because they give it for the oscillator before
they divide it down. Done properly, you get 6 dB/octave
improvement on close-in phase noise you as divide it down,
so the HF phase noise is bit better than at 448 MHz.

BTW If you are looking for a challenging project--may I
suggest a computer controlled synthesizer that covers the
HF bands with less phase noise than the HP8640 and spurs
at least 80 dB down? Even better if you can turn it
into a simple construction project for hams to build.

Yes we have. We sent a fairly clean transmitter to one of our Technical
Advisors with a high-end HP phase-noise measurement setup. We found we
were within a dB or two, worst case. I plan to do this once a year or
so, to keep our Lab-built equipment "self calibrated" against a known,
calibrated instrument.

I am a bit unclear as to how the color coding scheme applies to small RF chokes. The type of choke I am refering to look like small resistors and have colored bands around them.

I can see that the first and second band refers to a digit value as in a resistor but the multiplier band confuses me.

For example what value would a choke with the colors brown black and orange represent?

Any help would be appreciated.

A catalogue I have has a colour photo of a 4.7mH choke, and I think the
bands are yellow, purple, red - 4700uH = 4.7mH. I've actually got a couple
somewhere, but can't find them. Your brown, black, orange example is probably
10000uH=10mH. It seems logical, anyway, and is in line with a section on
colour coding in the ARRL Handbook - it's an EIA standard which can apply
to inductors, it states.

List Of Stamp Applications (L.O.S.A for short)
==============================================

If you have done something with the BASIC Stamp (big or small)
that you are willing to tell others please use the form below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Then e-mail the form to:

cj@algonet.se

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill in
the L.O.S.A form on the Web-page...

http://www.algonet.se/~cj/losa.html

The latest version of L.O.S.A is going to be posted to the following
mailing lists and news groups, I will update it approx. once a month.

Mailing lists:

BASIC Stamp Mailing List

Mews groups:

comp.robotics.misc
comp.home.automation
sci.electronics
sci.electronics.misc
rec.radio.amateur.homebrew
rec.radio.amateur.misc

5618. Voice via Light?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-30 00:00:00 UTC
From: rick@digalogsys.com
Message-ID: <49l0a6$k2f@homer.alpha.net>
Source record: 109281

I'd like to transceive voice via modulated light, but I'm wondering what the best equipment for such a set-up would be? I'd like it to be cheap and generic.

I'm thinking along the lines of something the kids could play with much like toy walkie-talkies... only using light. Visible light would be nice, maybe some high-brightness red LEDs, but IR would be fine. They'd have to have pretty *sloppy* collumation, since they'd be hand aimed "from the hip" as it were.

Some of my thoughts, so far...

o Use multiple LEDs mounted side by side for more power.

o Use the LEDs' own (integral) 'lense', so you'd only have to aim in the recipients' general direction. This would make it possible to "broadcast" in a roughly 90-degree cone.

Would it be better to use PWM instead of straight AM?

Are there any good (read, "tried it and it was fun") plans for similar devices already available?

I'd *really* like to be able to use some local landmarks as passive reflectors. That way, you wouldn't have to know where the other person was, as long as you could both shine your signals on the same target. Scan your horizon... What sticks up? Use it as a communication point. (I realize that for this I'd have to use higher power and collumation, but there's no reason two stations should have to be in direct line of sight if they can bounce their signals off intermediate objects.)

Is anyone already doing this? I'd like to hear from you.

(The entire spectrum of light [IR-UV] is open to experimenters, isn't it?)

Please do not perpetuate the myth that the '612 is a better (strong signal) performer than the '602. There are very minor differences, but the "602 is the better one (see QST May 1990 Tech Correspondence, p38 excellent and interesting letter from Bob Zavrel, W7SX).

Electrical near equivalents include; NE602D (8-pin plastic SO), NE602FE (8-pin Cerdip), SA602N (8-pin plastic DIP), SA602D (8-pin plastic SO), SA602FE (8-pin Cerdip).

You might try your local library if it's a good one.
NMSU library in Las Cruces NM used to have a fairly complete
collection of QST's, Ham Radio, Wireless World, and other mags
clear back into the early 1900's that was great for looking up
such projects.
Surely ARRL could provide reprints from their archives?

Colin, I'm pretty sure that we read them as micro Henries instead of ohms, so your sample choke would be 10,000 uH or 10 milliHenries.

>Thanks,

>Jeff, WA6AHL

Jeff,

Have you considered using television network burst processed for an accurate source. Any time your local t.v. station is broadcasting network feeds, their 3.57954545 signal is good out to upteen decimal places. About 10 years ago I phase locked a crystal oscillator to the crystal of a small solid state color receiver on the bench. Divide by 88 and multiply by 63 and you've got 5.000000000 Mhz. Turns out our local NBC affiliate kept the station locked to network black-burst even while they were originating locally . . . made for a rather simple way to get lots of zeros behind the integers . . .

Regards,

Bob, K0DYH

I have tried to use my 2m radio with an antenna about 10' away from my computer and my radio next to my computer, but all I get is static from my computer (I can't even squelch it out)!!! What is the best way to rf proof my computer case? I was thinking of covering all of the plastic parts (front cover, etc.) with metal door screen and spraying with metallic paint (will this work?). I was also going to put torroids on the power connections. Is this a good plan of attack? Thanx in advance.

5628. Help with Kenwood TH-31 TX pll problem

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-11-30 00:00:00 UTC
From: Jim Devenport <jdevenport@lanl.gov>
Message-ID: <49l2gs$8m8@newshost.lanl.gov>
Source record: 109291

Any Kenwood TH31 experts out there?
I'm having fits with a Kenwood TH31BT wherein it receives fine but does not appear to be maintaining PLL lock when trying to transmit. The TX LED comes on bright for about half a second, then it begins to flicker as though the battery was low or the PLL is not remaining locked. I don't have a manual so all I've been able to do is compare it with another operational radio, check for loose wires/bad solder joints etc. It's not the battery since it's being powered with an external power supply which operates the good TH31 just fine.
The radio died sometime during disassembly to change the broken case, but the only area where I could have trashed something is the small receive board just above the battery area. The only thing I can see there that might affect the transmitter is the dup/minus/reverse switch on that board. This switch works fine so far as receive functions are concerned.
Quick hints would be appreciated and provenance of a service manual would result in cash/swap reward.

>any place or person that sells these?

Doug,

Suppliers of (amateur) antennas sell these over here. Maybe they do it also
at your end. However, one thing: you have too use exactly the type
of mounting specified in your design (through the boom, on top of the
boom, isolated or connected..). There are correction factors to the element
lengths for each method. A successful method is mounting the elements
isolated through the boom with nylon rivets.

5634. receive overload with ts-520s

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-01 00:00:00 UTC
From: tomas@ra.cgd.ucar.edu
Message-ID: <49n9v2$9bj@ncar.ucar.edu>
Source record: 109297

Hello all,

I have an old ts-520s and live in a neighborhood in which several other amateurs operate. Unfortunately, the ts-520s receiver doesn't like it when there are strong signals present on the band it is tuned to. It gets mad and the agc kicks in with a vengeance---even if the strong signal is several 100 kHz away.

I've tried using the attenuator button (20 db); not surprisingly, this helps a little. I've also tried turning of the noise blanker (thanks to the reader who provided the suggestion); not sure if this helps or not yet. The less than acceptable solution I've found is to disable the agc when it starts throwing a tantrum. I am in search of suggestions/answers:

1) Is this a well known problem with these old rigs?
2) Is there a mod that will/may help?
3) If my poor uncle were to leave me several hundred dollars, are there used rigs out there that deal with strong signals better?
4) If my rich aunt were to leave me several thousand dollars, are there new rigs out there that deal with strong signals better?

By the way, I operate cw almost exclusively (as do my neighbors) and the rig does not have the cw filter installed.

We had TS-520 and IC-735 side by side during the 1994 field day.
TS-520 showed strong intermods at 80m in the evening while 735 had
none, even with RF preamplifier on.

Most likely, the overloading element in TS-520 is the mixer. If the
mixer is base on MOSFET, perhaps substituting a different type with
higher power would help.

It is also possible that the quartz filter has insufficient
out-of-band attenuation.

One solution would be to rewind the RF input coils for higher Q. I
have seen it done on FT-101ZD, and the difference in intermods on 40m
was spectacular. This modification may not help you much if your
neighbors operate close to your frequency.

Perhaps the best choice would be to sell your TS-520 and buy
something more resistant to overloading, e.g., TS-830 or IC-735.

5636. Re: How do I keep my computer from spewing rf?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-01 00:00:00 UTC
From: kferguson@aquilagroup.com
Message-ID: <49ngis$c5r@mack.rt66.com>
Source record: 109299

Most effective way to prevent computer from generating RF:

Find switch on computer marked I O: move it to the O position.
This has also been shown to markedly improve domestic relationships,
and has been successfully applied to a host of electronic devices such
as televisions, and tranceivers. When applied to telephones it
produces an indiscribable sensation of tranquility and calm.

OK,OK...couldn't resist.

Ferrite chokes can't hurt.. but one thing often lacking is good
bonding between pieces of case.

Yes the power cable can act as an antenna for noise generated inside
of case..same for vid cable, keyboard, printer, modem, mouse, etc. It
can't hurt to insure that the outlet you connect to has a good
connection to your station ground.

Make sure you screw down all those connectors...a lot of experimentor
types tend to leave them loose, and that is often the connection for
the cable shields.

I once resorted to installing pieces of clad board in the empty
drive-slot covers, and bonding them electrically to the rest of the
case. (though the problem I was fixing was that the computer was being
crashed by RF from a commercial broadcaster....PC was used in his
station's studio)

Make sure you have the covers on all your unused expansion slots.

Aluminum foil and spray contact cement are cheaper than fancy
conductive paint.

Also try pulling out accessorys (inc. keyboard and monitor) and see
if you can narrow down the problem..

If computer has "turbo" switch, see if problem goes away at low speed
setting.

Try everything you can think of....Be sure to post story if you lick
this problem.

I built some units about 15 years ago that did just that, using IR leds. You can use a simple VCO like the NE566, and use your audio to modulate it. As I remember it, I used a freq. of 455KHz, built a simple receiver using 455KHz IF transformers and a standard FM demod chip from Motorola. You can indeed get more range with multiple LEDs. Its easiest to run them in series, but the ir ones take about 2v each so the number you can put in series depends upon your supply voltage.

As a second thought there might even be some kits available -- I'll keep my eyes open.

Good luck....Jay (KI7RH)

Thanx for all the replies. I have a plastic front on my case so I will shield that. I will also replace all of the screws that are missing (8 of them I think (there's actually on 1 screw holding the cover on!). I will start with putting toroids on just the power cords and if doesn't cure it I will put a toroid on ever single on of those cables (9 of 'em, I just counted). Thanx again

>
>73, Drew Diamond, VK3XU
>

Drew is right... I've got the specs right here. The NE612 is
a "low power VHF monolithic double-balanced mixer with on board
regulator" (like the 602 but with the following differences:
612 is capable of signal frequencies of up to 500 MHz with a
gain of 14 dB at 49 MHz.
Whereas the 602 is capable of operation only to 200 MHz with a
spec. gain of 18 dB at 45 MHz. So it depends on what frequency you
want.

You can get NE602AN in small qty. from JDR Microdevices for $1.95 (old
catalog price may have changed).
JDR sales # 1-800-538-5000

Jake, I have not seen the Nov. issue of CQ. However, my bet is that it's the "RK-20 Tri-Tet Transmitter for Three Band Operation " by George Grammar, QST April 1935, P41 to 44. Uses a big fat RK-20 tetrode in a rock-crushing single tube 50 W power oscillator. Also see, if you can find a copy of;

"What's a Circuit" by George Grammar, QST Oct. 1935 P19 - 23 & 78.
George discusses "some problems encountered in building a simple oscillator amplifier transmitter".

BTW, IMHO the material written years ago by George Grammer must be some of the most lucid, well researched, easy to understand, and enjoyable technical material ever to appear in radio journals.

73, Drew Diamond, VK3XU.

Hallo

a friend has got a Philips VHF power tube YD1303 and he would
like to have some data sheet or hints where to find further information.
This tube was possibly intended for a PLISCH TV transmitter with
a few hundred watts at 400MHz.

Further informations would be appreciated very much.

The transmitter was probably also published in the ARRL Amateur's
Handbook for a number of years, libraries are more likely to have
that than the old QST.

5646. How To Repair Ceramic Switch?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-01 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <49p361$6p3@crash.microserve.net>
Source record: 109309

I have a ceramic switch wafer that I need to repair. One of the fingers is badly burned and melted away where it used to contact the rotor. The rotor itself looks OK.

The wafer is a standard size, a little over 2" diameter, and I have other wafers I could salvage a finger from. It's easy enough to drill the head off the rivet and remove the finger, but how to mount the new finger on the wafer?

Does anyone know if there's a specific size screw or other type of hardware that can be used for this?

Tnx & 73,

Jack WB3U

>
> --
> 73 & ttyl Morgan Patterson

The most likely cause of computer interference is the cabling. I use
my 2m radio next to my computer all the time with no trouble. Try
a large ferrite bead on each cable going into the computer.

Make sure all computer case screws are tight. If the screws are missing
like they are on 90% of computers that someone has been into several
times, the computer may spew forth vast quantities of RF.

If the computer passed the FCC Class B requirements in the US or
whatever you have as an equivalent, you should have no trouble.

Most IBM clone cases are metal, so further shielding shouldn't help
much. I don't know about other types of computers.

If your 2m rig is a plug into the power outlet type, you may need to
use a different power circuit than the computer uses.

Cheers,

Jim Goecks WA7UKS

>----oOO-----OOo---

Morgan,
The toroids are a good idea, put them on every cable coming in or
out of your machine. Put them as close to the computer end of the
cable as you can get them. If you have anything else with a computer
in it (tnc, etc.) put them on it, too. Not sure about screening the
case, but a good metal case would probably help too. Mine got a lot
quieter when I went from a plastic case to an all-metal case. Maybe
if you screen it real tight and ground the screen to the case it
might help.
Good luck and 73,
Kerry Miller - WD5ABC

: double-sided circuit board (part of an IBM PC AT); this is the most
and (hot air)
: I just thought of this technique today and was delighted to see it work
: so well. A similar technique with a propane torch is sometimes
: suggested, but it is more likely to scorch the board.

I often use a small profane torch to remove 244s and 245s from blown up PC multi-io cards. I don't care if the board gets scorched. (It does, lemme tell you, I've had boards igniting, do this outside.)

My philosophy is - if you're repairing the board, i.e. NO SCORCHING, cut the legs off the IC and remove individually. If you manage to pull out just one through hole, you'll be sorry. If you want the IC, not the board, wothehell, use the torch.

I heat the IC leads, then whack the board against the concrete floor.

I'd like to get a thread started on the cheap and easy ways to do prototype PC boards. I started asking questions on the CAD newsgroups and those folks are so bound up with workstations and thousand dollar autorouter programs that they just don't understand those of us using laser printers and fishtank etchers. I've gotten some damned good advice and some absolute trash.

My proposal is to start three threads: PCB software, PCB resists, and PCB etching. If anybody objects to me starting these threads in this newsgroup, say so now. If anybody has other major topics they'd like to add to the threads, say so now.

Otherwise on Monday morning...

WHich mods do you want? How to tune them and use them on voice or
as rptr or what????

The MSTR IIs can be easily retuned into the 2mtr band.....after
that, there are LOT of things you can do with them...

...And I'm sure CQ gave it a fair, and unbiased review. Yeah, kind of like the emphatic review I read by Paul Carr on the TS-950SD a few years ago. I bought the rig based on CQ's review. The result? I unloaded it six months later after suffering a BIG financial loss on it. I suspect the reason CQ isn't honest in their reviews is the thought of loosing a major advertsing client.

The ARRL may have their faults, but they've got the confidence to give an unbiased review of products in QST.

Does Ten-Tec still sell the 6M transverter kit they offerred a couple years ago? Does anyone have any experience with it? I believe it uses a 20M IF, right? I'm thinking it might be an interesting companion to a 20M SSB QRP rig.

Comments? Opinions?

Thus spake Morgan Patterson (VE6MRP):
>I have tried to use my 2m radio with an antenna about 10' away from my
>computer and my radio next to my computer, but all I get is static from
>my computer (I can't even squelch it out)!!! What is the best way to rf
>proof my computer case?

An easier solution might be to move the antenna. Sometimes that's all
it takes.

If that doesn't work (or isn't feasible), ferrite chokes on all cables
exiting the computer might help. That includes the power cord, BTW.

I sold computers at a local dealership for about a year.
We also built custom computers as well. I was hired because
I had experience building computers from scratch. In March
of '95 we picked up the PB Line and man was I amazed. We
discovered that PB was putting very slow hard drives, very
slow video cards, and other parts that were not what I would
call "current". Our 486 DX2-66 computers would exceed the
performance of PB's Pentium systems up to 75 Mhz. We also
built 486 DX4 80 & 100 systems that blew the socks off PB's
Pentium 90 & 100 systems. What gives??? Their poor
supporting hardware (HDD, HDD controller, Video controller)
seems to bottleneck what is otherwise a fantastic processor.
As far as service was concerned, when someone had a problem,
we simply exchanged the computer for up to 1 year!! We were
the #1 PB dealer in the area so we could easily make PB eat
it or drop their line!

My suggestion to computer buyers is to build your own!! If
you don't know how, find someone that does. You can then
hand pick each piece that goes into it and get a good
performance machine. Another rule of thumb I use is to NEVER
buy a computer based on the software packaged with it. It is
only a sales gimmick!

Price wise custom built computers run a little higher but the
performance advantage is worth it in the future. And by
hand picking good, brand-name parts, you'll have less service
problems.

btw...we commonly referred to the PB as our best POS (Piece of
$hit) computers!

John,
I believe the IF is way down at 11KHz, that's how they get the
DSP to work. Lew McCoy did a good review of it in a recent magazine,
I think CQ, but it may have been 73. Heard one on the air last week,
the guy sounded clean, but real bassy. The dsp on transmit may take
more fine tuning than some people are willing to learn how to do. I
know there is a similar option on my Yaesu FT-990 and if I set it up
wrong, I can sound pretty bad. Looks like a great rig, though.
Wonder if the next generation will have the dsp in the 9 MHz IF???

From: howse@cleo.murdoch.edu.au
Message-ID: <49p40pINNeog@newsman.murdoch.edu.au>
Source record: 109323

Advice is sought about the HEMT-PA design (10-93) by DB6NT and published by DC0DA which uses a BAT15 diode to monitor power output.

Can anyone provide information about the impedance of the meter attached to the BAT15 output monitor (eg 20 Kohm/volt) and what the range of typical readings might be for particular power levels?

I am also chasing any Australian source of calibration of a waveguide detector to get a better idea of where we are in the power stakes and of a directional coupler suitable for measuring return loss. Can any Aussie reader please help?

Thanks

73

>>If they had an '8662, it would be a different story.
>
>73 from ARRL HQ, Ed Hare, KA1CV, ARRL Laboratory Supervisor

In terms of free standing oscillators (not phase locked to anything),
yes indeed you would be doing very well to even get within 10 dB. of the
8640's cavity oscillator, since the Q of the cavity is so much higher
than any tank circuit you are likely to be using. This is important
if you are interested in phase noise at say 20 kHz. offset from the
carrier. Note that at that offset, the 8662 is *not as good*!. BTW,
if you are worried about phase noise at say several MHz. from the
carrier, then the HP 608 is better than anything else that has ever
been made in a general purpose signal generator, because it has a
tuned amplifier stage following the oscillator. Close in, at 1 kHz.,
the 8662 is very well phase locked to a low noise crystal oscillator,
hence is much better than the 8640 could ever hope to be.

So how do we solve this dilemma? Simply build two copies of whatever
it is you are testing and compare them against each other. Then you
don't have to come up with a reference source. This is the way most
measurements in industry are done.

What is known is this: the US Naval Research Laboratory tested our receiver
and measured an average error of 50 nsec. compared to UTC. This is the best
performance that they have measured, at least in the unclassified domain.

>about to use it as a frequency standard reference without at least an hour's
>averaging time.)

Precisely. We average for around an hour when using quartz oscillators.
We suggest a day or two of continuous operation before expecting maximum
accuracy. For our cesium based GPS systems, we average for a week! to remove SA.

HP makes a family of super bright red LED's with beam widths as low
as 3 degrees which results in a photometric intensity of 15 candlepower
and is quite visible, even in the daytime. Short wave IR devices are
cheaper for a given intensity but may not be as much fun to use since
the beam is invisible. You will find such a device to be quite
interesting to fool around with as you learn the 'sounds' of various
light emitters such as streetlights, car headlamps reflecting off
the pavement, aircraft propellers reflecting sunlight and the beating
of insect wings. You will defiantly want to provide a tone modulation
source for alignment and optical 'radar' (lidar officially) experiments.
>
>Some of my thoughts, so far...
>
> o Use multiple LEDs mounted side by side for more power.

You will always want more power :-)

> o Use the LEDs' own (integral) 'lense', so you'd only have to aim
> in the recipients' general direction. This would make it possible
> to "broadcast" in a roughly 90-degree cone.

There is a tradeoff between beamwidth and irradiance. You trade off
convenience for range and signal to noise ratio.

>Would it be better to use PWM instead of straight AM?

Probably not. PWM will occupy a greater bandwidth than AM and therefore
have poorer SNR for weak signals. PWM can provide processing gain and
an enhanced detected SNR for strong signals but most likely is a poor
tradeoff in your application. The linearity of the LED's to AM modulation
is certainly adequate for this application and the detectors are quite
linear over a dynamic range of greater than 10^8! Here are some useful
guidelines based on the assumption you are using ordinary components
widely available and you are trying to keep the project reasonably simple:

At night you will be limited by the preamplifier noise figure unless
you have street lamps to deal with in which case you would defiantly
benefit from a Single Sideband (SSB) scheme with a suppressed carrier
frequency of at least 15 kHz. Not as hard as it sounds but probably
not worth it in your case.

During the day you will be shot noise limited due to the current generated
from background light falling on the detector. This will improve dramatically
as you reduce the detector field of view.

An optical bandpass filter such as red cellophane gel will significantly
improve the performance during the daytime by reducing background light
falling on the detector but will reduce performance at night by attenuating
the signal. Obviously the narrower the optical bandpass the better but
any practical filter (even big $ interference filters) will result in
a system substantially shot noise limited during the daytime, unless
the receiver design is really horrible.

You won't do much better for a preamp than an ordinary JFET input
op-amp such as an LF-353 with as large a feedback resistor as you
can manage. About 100K ohms for daytime operation and at least
10M ohm for nighttime. Resistor should be low noise, defiantly not
a carbon composition but a metal film is OK. Just about any 1% tolerance
resistor will be reasonably low noise.

Operate the detector with at least 5 volts of reverse bias.

Use a collecting lens for the receiver. It will both greatly concentrate
the received signal and reduce the background illumination reaching
the detector. Radio shack sells a plastic magnifier for about a buck which
is around an inch and a half in diameter and has a focal length of about
two inches; just about perfect for a starter!

Roll of the audio response below 200 Hz or so to stop most of the
1/f crud generated by the preamp and detector, especially if it's
a crummy one.

>I'd *really* like to be able to use some local landmarks as passive
>reflectors. That way, you wouldn't have to know where the other person
>was, as long as you could both shine your signals on the same target.

This will require a pretty decent setup, even at night. Consider using
a laser to cheaply generate illumination with a narrow beamwidth; no
sense in having most of the light miss the reflector! You will also
want to use tone (CW) signalling and a narrow audio bandpass filter
to improve the SNR. A receive aperture of several inches is in
order for reflectors more than a couple of hundred yards away. BTW,
reflective stop signs and car tailights work pretty well up to a few
hundred yards.

>Scan your horizon... What sticks up? Use it as a communication point.
>(I realize that for this I'd have to use higher power and collumation,
>but there's no reason two stations should have to be in direct line of
>sight if they can bounce their signals off intermediate objects.)

The math and physics required to do a decent job of system engineering such a system are fairly simple and really do quite a good job of predicting real world performance, at least at night. Email me if you're interested in further discussion.

>Is anyone already doing this? I'd like to hear from you.

Ok.

>(The entire spectrum of light [IR-UV] is open to experimenters, isn't it?)

Yes, as long as you don't annoy or frighten anyone :-)

5673. Note for Users of FilDes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-03 00:00:00 UTC
From: blombard@iu.net
Message-ID: <49sm2a$4uj@cc.iu.net>
Source record: 109186

Users of my program FDS (FilDes) may be interested in knowing about
a program that I just uploaded to the archives at ftp.ee.ualberta.ca,
the main archive where I keep FDS124.

The program is a companion utility called TS2ARD. It is in a zipped
archive with a DOC file called TS2ARD.ZIP. It is available in
the directory /pub/cookbook/softw/ibm.

TS2ARD converts the Touchstone files written by FilDes into ARRL Radio
Designer format. That allows you to analyze these filters using ARD.
Why? You can display attenuation vs frequency, group delay, input/output
match, or anything else you might want to know about the filter. You
can optimize the filter's cap values, given a coil you might have
already available (or coils based on an available caps...). In short,
you can use the combination of FDS and ARD to make sure you can build
the filter, and that the filter you can build is the one you need.

As with FDS, this program is freeware.

73,
Bob

>
>I simply don't have any kind of info on this GaAsFET.
>

It's unclear as to whether you have the S parameters for the
MGF 1402 at other frequencies or not.

The data sheet I have lists them down to only 500 MHz.
You might extrapolate these data down to 150 MHz by curve
fitting, but it would be very crude. In fact, I tried it
with the S11 data and a cubic fit and get a reflection
coefficient greater than 1. This of course, is possible,
but not good news.

The best approach is heuristic, ie cut-and-try. My approach:
Build the lowest loss input circuit you can. Load the hell out of
the drain circuit (4:1 transformer for load). Adjust the input
network, drain voltage and current for best NF. Enjoy.

From my point of view, you can use a standard
Kenwood/Yaesu/Icom/Alinco/what-have-you transceiver, and modulate light
with your voice. I'm a physicist...

What frequency are you looking at? Visible light? IR? UV? UHF works fine for
me :-)

You could take apart one of your TV remote controls (IR) and modulate the IR
LED there.

>Regards, Wes -- N7WS

My impression of the role the 8662 plays in the HP 3048 phase noise
test set is that it interfaces with the 11729 down converter. It supplies
clean 640 MHz. to it from a special rear panel output available as
an option. The 640 is multiplied to microwave frequencies and used
to down convert the microwave signal source to be measured down to
the 640 to 1280 MHz. band. The 8662 is then locked to the
down converted signal. In most cases, the 8662 is cleaner
than the down converted microwave source, so it is a good match.

When measuring HF sources, the 8662 is relatively useless. Either
the source is too good for it, or the source is so noisy you can
measure it with a spectrum analyzer or modulation domain analyzer,
which is far easier.

At offsets like 20 kHz., you reach the noise floor
after a few octaves and no longer go down 6 dB/octave.

I am in desperate need of a pair of cables that go between the display unit and the RF unit on the HP 8505 Network Analizers. I just purchased 2 of these and cannot use them because I don't have the cables. Please point me to where I can get these. The cable has 5 or 6 coax connections and around 17 other connectors.

> Bob, K0DYH

Bob, what you were able to do back in the mid-'80s may not be possible
today...a lot of (if not most) broadcast stations resync everything to
their local master oscillator, which may not be a rubidium oscillator
and/or may not be held to the old network frequency tolerances (but are
within FCC Part 73 tolerances). I've observed consistent differences of
several parts in 10E-7 between the burst signals broadcast by the network
affiliates in my area, and I suspect this is true elsewhere. Without
detailed info on a given station's engineering practice, I'm not sure you
can count on a standard derived from TV color burst being much better than
what you could get from WWV or WWVH derived standards.

FWIW to Jeff, I'm on the verge of building the WWVB receiver and comparator
from
the 73 magazine articles. I'm holding off on the ovenized oscillator
portion, as I do have an old GR1115B crystal frequency standard which I
plan to use instead. If you're looking for general info on WWVB, you can
look for a copy of NIST Special Publication 432 (Revised 1990) which you
ought to be able to obtain from your local GPO bookstore.

This is merely the announcement that I am starting three new threads in this newsgroup. There will be:

PC Board Proto: Software
PC Board Proto: Resist/Developer
PC Board Proto: Etching & Plating

If you all run across a question in another newsgroup about PC board prototype construction, would you please refer them over to this group? I've been collecting information for about three months from half a dozen newsgroups and can't remember from day to day where the threads all went.

Thanks for sharing your expertise.

>prototype PC boards.

Funny you should ask, your timing is impeccable.
I just posted this yesterday on sci.electronics,
here we go....
By the way, for anyone not familiar with the product, PnP Blue is a plastic 8.5x11 sheet similar to a transparency, but with a blue coating which also transfers to the copper. It's made by Techniks Inc, Ringoes NJ, and available from All Electronics.

There's been some talk about making boards with various toner transfer methods lately, so I thought I'd post my experience.

I just finished my first PC board using the PnP Blue toner transfer sheets.
I'm quite happy with the results.
Here's how it went:

Did the artwork with Easytrax, did some test prints on the HP LaserJet 4+ and determined the
minimum size paper it would feed.

Cut a piece of PnP Blue to the same size, and printed. The printer had no trouble feeding, and printing on the sheet. So far so good.

Cleaned the board, used an SOS pad, rinsed, then cleaned with isopropyl alchohol.

Heated up the iron to the middle range of steam.
Placed sheet on board and applied the iron. Big problem!
The sheet wrinkled, crinkled and did everything but melt (probably would have had I continued)
I decided I was using too much heat.

Cleaned board again (it was a bit harder this time, due to some of the toner transferring.

Cut another sheet and printed, again printer performed beautifully.

This time, I set the iron at half the temp (just below the steam setting)
Aligned sheet, applied iron, and it worked. I ironed for about 1 minute, which might have been a tad to little, as one of the 30 mil traces didn't quite transfer in one spot. An easy touch up with a Staedler 313 Permanent pen, and I was ready to etch.

Earlier, I had made a bubble etching tank out of an old narrow square plastic container, an aquarium pump and a flat aquarium bubble rock. The local electronics shops want $130.00 for
a

bubble etcher! And it's not that much different from what I made.

I mixed up a batch of ammonium persulfate 250G/1L of hot tap water, and etched away.
The result was a very good looking board for my first attempt!
Drilling was tougher than I thought, I used my Dremel tool in a Dremel drill press stand with a #68 bit. I found the bit would wander a bit as it came into contact with the board, but that if I pressed faster, the bit wandered less.
The 20pin DIP will be a bit tough to insert, as a few of the holes are off a tad, but the 8 pin DIP, and the rest of the holes are close enough.

If anybody has any drilling tips, I would like to hear them.

I don't know if the circuit will work, but the board sure looks good.

Sorry for rambling,

Steve VE6STV

Source record: 109205

Just recently made a 2m 6 element yagi beam (two of them). The sliding choke or balun is giving me trouble. One has a SWR of 1.5 and the other 1.7 . Both are cut exactly the same utilizing metal jigs. Holds are drilled exactly the same via metal jig. Floow who helped me said can be used either vertical or hirizontal.

If we can't get SWR better, how could we redevelop a new/different matching devise without a plan ? It is supposed to tune to a 1.1 SWR, and have a 9+db gain.

Also, used my MFJ cross needle meter, and also my MFJ antenna system analyzer...both sho slightly different SWR..Any comments or ideas. I probably have not explained myself properly. Thanks for reading this. Merry Christmas and Happy Holidays To All, and Peace On Earth.

From: ed@fore.com
Message-ID: <49vdlc$a90@baleen.fore.com>
Source record: 109207

I did some playing some years ago as a data transmission link.

Checkout Radio Shack experimenter guides / engineers notebook perhaps its called,
couple of nifty experimenter circuits in there.

A few things I did find out.
IR leds put out better and IR filtered detectors are easy to come by and have
the advantage of filtering out some of the external light.

Cheap kids binoculars can also be used as a alignment and receiving aid.

Use 2 pairs, modify right side for the photo detector and then the other side can
be used to 'scope' in on the signal source. This will provide some optical gain,
but you may want to play with the focus, too sharp of a focus and it will be hard
to get the image to fall on the detector reliably.

I came up with a gimmic to collimate and align the IR beam. Use 3 leds, red,IR,
and green. Put these in a small tube or box that uses a fresnel lens at the
front to focus them. I was able to project spots for miles with this method
and some hi power leds.
rIg
*** Put the leds in a row, close together. Red, IR, Green.

|*----}--------- Beam
leds lens

You can project the images on a wall 3 feet or so, and adjust the focal distance
or view it from the front and adjust the focus until you see red & green both
in the lens (the leds will look huge and bright) Do this until the red and green
just start to get cut off on the sides of the lens, this will provide the best
brightness at a distance. Then you will be able to find the center of the beam
at a distance by knowing if you see all green, go left, all red, go right, both
red & green, you will be center in the IR beam.

What this does at a distance....

R IR G
/ | \

/ | \

/ | \

/ | \

_
O_O < binocular detector

P.S. Paint or line the LED box with white paper or something non flammable if you use it outside in the sun, fresnel lenses are very good heat focusers in sunlight.

We (me and Rob PE1KHX, a fellow ham in the area) are about to start with this experiment also. We're in the phase of collecting/buying the needed components now, and already have the PCB's and Gunnplexers.

One thing is rather unclear to us: What type of (PC-LAN) interface cards (2Mb/s) are suitable to connect to the Data Link transceivers? I have ever seen any 2Mb/s LAN cards, except ARCnet but these don't have "AUI" interface.
Would it be possible to just use plain 10Mb/s ethernet cards (AUI or 10base-T interface), can they be "brought down in speed" to match the data link transceiver capabilities.

We don't need to cross large distances, 2 miles at most.

Anyway, we'd appreciate to share any experiences too.

Please post to this newsgroup or Email me direct at my QRL.

From: DICENSODJ%DFL@pcmail.usafa.af.mil
Message-ID: <49voub$kvj@usafa2.usafa.af.mil>
Source record: 109211

Anybody had experience with the MFJ QRP rigs?

I'm looking for a portable rig for Rocky Mountain 4x4 camping trips.
How good an idea is the MFJ QRP SSB rig?

Are the MFJ rigs worthwhile, or should I just mount my trusty,
bullet-proof, reliable old Atlas 210 under the dash and forget about
MFJ?

Also, is 20m too crowded (General portion) for the MFJ QRP SSB rig's
primitive receiver, or is it selective enough to be useful?

Should I go with a 15m MFJ rig instead, due to limitations of the rig
itself?

Thanks for your comments!

>Otherwise on Monday morning...

Hmm. Well Jim you seem hell bent on STARTING A NEW GROUP. FYI UNIX no longer has the lock on the capture/layout market. The top 2 UNIX player are now releasing NT version, one of which I'll probably buy. The really big problem though is the parts. Have you ever "homebrewed" a board that takes TSOPs? Just wait until BGA goes mainstream, theres no way in hell you can whip up a prototype board to eval those things in an afternoon. I don't want to sound discouraging but I have no problem with 50 mil SOICs or 0805 discretes. Its just that you can't route them very tight or run them very fast without your internal layers.

I need the "pretune assembly" and the "VCO and amplifier assembly" for the 350-450 MHz HF loop in an HP 8660C synthesizer. Thanks for your help.

Same here. I downloaded a copy of easytrax.zip and it looks pretty
interesting. Unfortunately, it won't print to my HP inkjet. Anyone
know a freeware/shareware layout program that will? Alternately, is
software available to allow an inkjet to emulate a laserjet?

HamComm 3.0 supports AMTOR ARQ & FEC modes. As AMTOR is almost the same as
SITOR it also copies SITOR-A/B and NAVTEX which uses SITOR-B.

Here is a sample NAVTEX transmission i copied last week (11/28/95):

Hi Rick, I saw your post and thought I'd jump in.
I don't own stock or anything but for what you
need you can try contacting the technician at
RADIO RECYCLERS in Milwaukee, WI. They have a
good deal of old parts like that in there bins.
They do tear apart a lot of old radios and such
and gather all the remnants. They also buy up
lots of inventory of parts (I saw a complete
line of B&W mini-ductors, pilot lamps, tubes
and ceramic/phenolic rotary switches). The owner
Neil Lawton will patch you thru to the right
person to talk to you to determine the part
you need (they should be able to measure the
capacitance as well). You can find there ad in
ham magazine classified (I don't have number
handy)....good luck and 73....

```

Sorry, there are no formal noise data so you'll have to do it by
cut-and-try as Wes, N7WS suggests. The MGF1302/1402 is still one
of the lowest-noise GaAsFETs for use at lower VHF and UHF.

: >>performance of the '8640.

It looks like I've missed some interesting posts while our newsfeed's
been broken. I've not seen the earlier parts of the discussion so my
comments could miss the target somewhat...

The above is true of all phase noise test systems!

: >Good point. Interestingly, the Handbook stated that the 8640B "has a
: >much cleaner spectral output than most transmitters", and so would be
: >adequate in this application. I wonder if the ARRL's Lab has compared
: >the results of the 8640B method with those from commercially available
: >phase-noise measurement systems? How much worse is this technique? Its
: >virtue is that, if you already have an 8640B, it's very simple.

The 8640 isn't some wonder gold-standard, but they're a lot easier to
get hold of than 8662s and 8663s !

In considering phase noise testing, the offset freq range of interest
has to be decided on carefully, the 8640 is particularly good far from
the carrier... incidentally, don't forget the old valved 606 which had a
tracking tank on its output stage - gives very low broadband noise floor.
I modified one for FM so I could lock it back in the days before "off the
peg" phase noise testers.

Of course, a really good vcxo custom designed for a spot frequency can
always be made, and should be able to outperform all phase noise testers.
you pay in several ways for frequency coverage.

: Yes we have. We sent a fairly clean transmitter to one of our Technical
: Advisors with a high-end HP phase-noise measurement setup. We found we
: were within a dB or two, worst case. I plan to do this once a year or
: so, to keep our Lab-built equipment "self calibrated" against a known,
: calibrated instrument.

I've plenty of experience with both approaches, and the IC765 plot
was done on one of our fully traceable, calibrated, phase noise systems.

For HF radios, the 8640 is plenty good enough to outperform existing
radio's synthesisers. A few VCXOs could be built for less than an 8640 for
state of the art performance at spot freqs - when testing synths, you can

take the mountain to mohammad.
With the VCOs you can always build a pair and measure their JOINT
phase noise as a proof of performance, as Zack suggested for a pair of
8640s. The only way to prove a state of the art clean source may be to
build a pair...

I bought a Ten Tec 1208 20 meter to 6 meter transverter at Dayton'95.

Costs $90.00 and works real well. Goes together pretty easy. Has 6-8 watts
out for 5 watts in.

A friend of mine (KA3NLV) is a machinist. I was aghast when he showed me how to keep a drill bit from wandering (me being a sparky type)! He chucked the drill bit all the way down to within 1/4 inch of the end of the bit in the drill press. He explained that bits are made of hardened steel and the cutting edge is quite strong and will not be harmed. Besides, in this application you are never going to use that bit for more that 1/8 inch or so depth anyway.

Another neat device he showed me was a drilling device (I don't what is called,but I seem to recall seeing one at the local hardware store) that has a shank about 3/16 inch but it tapers down and has a VERY short drill bit that is considerable smaller in diameter (about the right size for PC board holes).

>
>I would waste an entire ink pen on just one board,i'm sure.It's not >really practical to use it!

I have used many methods, but I have found that plain ol'
black electrical tape works well for large areas (> 1x1 cm).
For smaller "large" areas, some electrical parts houses
sell a black paper tape, almost like narrow masking tape.
It is very similar to artwork tape for drafting. However,
if the ferric chloride gets too hot, the adhesive has a
tendency to soften, causing _problems_.

Good Luck,

There are several of us here in the area who are using EAGLE
for PC board design and schematic capture. It is a low cost
package ($500 for 16 bit , $1197 for 32 bit versions) with a
really excellent autorouter - the best I have seen. It is the #1
PC-based PC board design package in Europe. (It is a German
import, but you would never know it.) It's main weakness is
the lack of heirarchical schematic design. I have used it to
do my DSP boards (see the '96 ARRL Handbook).

I bought it after looking at a lot of different packages, and I
don't regret it.

At the time, I almost bought the Orcad package with their
router which would have cost $3000. But, Orcad has a $600
annual "maintenance fee." So for $1200 for Eagle, I figured
I could buy it, use it for two years, and if I didn't like it, throw
it away, buy Orcad, and not be out any money. In other words,

two years' worth of "maintenance fees" pay for Eagle, which
has free support.

EAGLE is distributed by Cadsoft, 800-858-8355

It's a center drill. Also when going for best accuracy it's best not to have
the workpiece too far from the drill point when it's at rest.
(Bring the table up to the tool) This will reduce wandering caused by spindle
and colunm flex and slop.

Source record: 109087

Dear Jim,

I have found that using PCB software like Easy-PC Plus, then outputting to a laser printer using OHP transparencies it is quite simple to get artwork good enough to produce PCBs using a UV light box. The keys is to dramatically reduce the exposure time, by experimentation. One or two tips,

1) Always put some writing onto the artwork, so that it is easy to work out which way round its supposed to be as you look at it the wrong way round, if you see what I mean.

2) If you want the artwork to be a be more permenant and prevent scratching, spray with Scotchguard or hairspray or similar, note the hairspray trick works for Letraset as well.

3) For artwork requiring higher density black, ie microwave stuff, print it twiceand overlay carefully.

4) PCB Photoresist you can by from RS etc, is a waste of time and money cause youï¿½can't apply it thin or even enough.

Just a few tips from my experience.

Cheers.

Hi,

I'm trying to build an IF amplifier using JFETs. It's a common source configuration with a parallel LC tuned circuit in the drain circuit to VCC.

Naturally the source resistor goes to ground, but how do I calculate its resistance?

I've seen how to calculate source and drain resistances but not when there is a tuned circuit in the drain.

The resonant frequency of the LC circuit is 50MHz.

Any help would be most gratefully accepted, thanks.

Yeah, but the fun part is biasing it for linear operation. For the most part, our options in trying to get low distortion with such toys are:

1. Go out and buy a hyper-expensive IR LED for which spec sheets are available (and reasonably accurate).

2. Use junkbox LEDs and tweak obsessively until linearity is achieved.

3. Build ten times as much circuitry and go digital.

:

Sorry about that glitch. There should indeed be decimal points at
the beginning of each line below 1.0GHz. It seems that many types of mailer
software will ignore a period at the beginning of a line.

Yes, the angles >=180deg are unusual, but I thought it better to copy them
exactly as printed in DUBUS. All respectable software should be able to handle
them correctly.

The values should extrapolate quite smoothly to lower frequencies, because the
device itself tends towards simple "triode" behaviour at LF. Still, it's good
to have some genuine measured values for a change.

HamComm 3.0 supports AMTOR ARQ & FEC modes. As AMTOR is almost the same as
SITOR it also copies SITOR-A/B and NAVTEX which uses SITOR-B.

Here is a sample NAVTEX transmission i copied last week (11/28/95):

In terms of free standing oscillators (not phase locked to anything),
yes indeed you would be doing very well to even get within 10 dB. of the
8640's cavity oscillator, since the Q of the cavity is so much higher
than any tank circuit you are likely to be using. This is important
if you are interested in phase noise at say 20 kHz. offset from the
carrier. Note that at that offset, the 8662 is *not as good*!. BTW,
if you are worried about phase noise at say several MHz. from the
carrier, then the HP 608 is better than anything else that has ever

been made in a general purpose signal generator, because it has a tuned amplifier stage following the oscillator. Close in, at 1 kHz., the 8662 is very well phase locked to a low noise crystal oscillator, hence is much better than the 8640 could ever hope to be.

So how do we solve this dilemma? Simply build two copies of whatever it is you are testing and compare them against each other. Then you don't have to come up with a reference source. This is the way most measurements in industry are done.

It looks like I've missed some interesting posts while our newsfeed's been broken. I've not seen the earlier parts of the discussion so my comments could miss the target somewhat...

The above is true of all phase noise test systems!

: >Good point. Interestingly, the Handbook stated that the 8640B "has a
: >much cleaner spectral output than most transmitters", and so would be
: >adequate in this application. I wonder if the ARRL's Lab has compared
: >the results of the 8640B method with those from commercially available
: >phase-noise measurement systems? How much worse is this technique? Its
: >virtue is that, if you already have an 8640B, it's very simple.

The 8640 isn't some wonder gold-standard, but they're a lot easier to get hold of than 8662s and 8663s !

In considering phase noise testing, the offset freq range of interest has to be decided on carefully, the 8640 is particularly good far from the carrier... incidentally, don't forget the old valved 606 which had a tracking tank on its output stage - gives very low broadband noise floor. I modified one for FM so I could lock it back in the days before "off the peg" phase noise testers.

Of course, a really good vcxo custom designed for a spot frequency can always be made, and should be able to outperform all phase noise testers. you pay in several ways for frequency coverage.

: Yes we have. We sent a fairly clean transmitter to one of our Technical
: Advisors with a high-end HP phase-noise measurement setup. We found we

: were within a dB or two, worst case. I plan to do this once a year or
: so, to keep our Lab-built equipment "self calibrated" against a known,
: calibrated instrument.

I've plenty of experience with both approaches, and the IC765 plot
was done on one of our fully traceable, calibrated, phase noise systems.

For HF radios, the 8640 is plenty good enough to outperform existing
radio's synthesisers. A few VCXOs could be built for less than an 8640 for
state of the art performance at spot freqs - when testing synths, you can
take the mountain to mohammad.
With the VCOs you can always build a pair and measure their JOINT
phase noise as a proof of performance, as Zack suggested for a pair of
8640s. The only way to prove a state of the art clean source may be to
build a pair...

Sorry, there are no formal noise data so you'll have to do it by
cut-and-try as Wes, N7WS suggests. The MGF1302/1402 is still one
of the lowest-noise GaAsFETs for use at lower VHF and UHF.

Subject: Voice via Light?

I did some playing some years ago as a data transmission link.

Checkout Radio Shack experimenter guides / engineers notebook perhaps its
called,
couple of nifty experimenter circuits in there.

A few things I did find out.
IR leds put out better and IR filtered detectors are easy to come by and have
the advantage of filtering out some of the external light.

Cheap kids binoculars can also be used as a alignment and receiving aid.

Use 2 pairs, modify right side for the photo detector and then the other side
can
be used to 'scope' in on the signal source. This will provide some optical
gain,
but you may want to play with the focus, too sharp of a focus and it will be
hard
to get the image to fall on the detector reliably.

I came up with a gimmic to collimate and align the IR beam. Use 3 leds,
red,IR,
and green. Put these in a small tube or box that uses a fresnel lens at the
front to focus them. I was able to project spots for miles with this method
and some hi power leds.
rIg
*** Put the leds in a row, close together. Red, IR, Green.

|*----}--------- Beam
leds lens

You can project the images on a wall 3 feet or so, and adjust the focal

or view it from the front and adjust the focus until you see red & green both
in the lens (the leds will look huge and bright) Do this until the red and
green
just start to get cut off on the sides of the lens, this will provide the
best
brightness at a distance. Then you will be able to find the center of the
beam
at a distance by knowing if you see all green, go left, all red, go right,
both
red & green, you will be center in the IR beam.

What this does at a distance....

R IR G
/ | \

/ | \

/ | \

/ | \

_
O_O < binocular detector

P.S. Paint or line the LED box with white paper or something non flammable if
you use it outside in the sun, fresnel lenses are very good heat focusers in
sunlight.

I'd say that you're best bet would be to relocate the antenna at a
distance greater than 10 feet away from the computer.
Some computers spew out less RF trash than others, not only due to the
quality of the case but the motherboard design (quality and number of
layers/ground planes) and speed.
If there's an alternate place where the antenna can be relocated to
which is a lot further away then that should be your first step.

>
> Peter Dettmann1/2 C V^2 = 2000 joules stored energy. That's big but not outrageous. Also, not cheap. Try:
Chicago Condenser 312-774-6666
Condenser Products Corp. 904-796-3561
High Energy Corp. 215-593-2800
Plastic Capacitors 312-489-2229

There are others, look in your EEM catalog. The above are some that I have had satisfactory dealings in the past. High Energy Corp, in particular, made me a 6000 J capacitor. Their one off prices are pretty good. some of the others want as much for the first one as the do for the first two on specials. All of them will need to know details about the application since there are many tradeoffs on terms of performance and cost.

>down converted signal. In most cases, the 8662 is cleaner
>than the down converted microwave source, so it is a good match.

True as far as it goes. The 640 MHz is used to drive the 11729/A/B/C
harmonic generator. The 640 MHZ is generated from the internal 10 MHz
standard by multiplication. There are, however, crystal filters at
40 and 160 MHz to clean up some of the multiplied junk. Harmonics of this
signal are used to downconvert a microwave signal to the range of
5-1280 MHz where the phase detector operates, using the synthesized
output of the 8662 as the reference.

When the input frequency is less than 1280 MHz, it drives the phase
detector directly and the multiplied output/harmonic multiplier is unused.

>When measuring HF sources, the 8662 is relatively useless. Either
>the source is too good for it, or the source is so noisy you can
>measure it with a spectrum analyzer or modulation domain analyzer,
>which is far easier.

Hmmm. We have some missile applications where it isn't good enough
at microwave either. But then, neither is the 11729. However, is there
no in-between at HF? Both the spectrum analyzers and modulation analyzers
use synthesized LOs. Are these better than high performance HF oscillators?
How do you measure phase with a spectrum analyzer? How do you achieve the
required dynamic range with a spectrum analyzer. This info would be very
useful to me.

5738. Schema-PCB design output

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-06 00:00:00 UTC
From: cozzi@nd.edu
Message-ID: <4a2pb0$b14@news.nd.edu>
Source record: 109101

I have been using a combination of Omation's Schema and
WinTek's Smartwork for schematic and PCB design for several
years. Now we are looking at the Schema-PCB package for
generating printed circuit boards. Up to now we have been using
a Houston pen plotter with fairly good results.
What I would like to know is what other people are using for PCB
layout. All the way from Omation/Tango Schema to the photo resist.

Is it possible to use laser printers on mylar/vellum?
Should I be looking for 600 DPI printers instead of 300 DPI
Is HP's Enhanced Resolution worth it
and on and on...

Any suggestions welcome.

Thanks

Did you leave a hole in the middle of each pad to help start the drill? I usually don't have too much trouble with the drill wandering if I do that. Easytrax has an option to adjust the size of the hole.

There are steel drills and carbide drills. Carbide drills are supposed to stay sharp longer while drilling abrasive material like fiberglass reinforced board. But they break so easily that I've never had a chance to find out if it's true. I get more use from the cheaper steel drills.

5740. Serial-to-Parallel Converter

I'm trying to find either an IC or a schematic for converting serial-parallel.

I own a solid state radioteletype decoder (circa 1980) designed to work with serial printers. However, my printer, like virtually all others is parallel.

Regards,

Brian Webb, KD6NRP

Brian,
Don't bother building one when you can buy one - about $90 from
Global Computer Supplies 800-845-6225.

Of course, a used serial printer at a hamfest would be cheaper than that.

You need a Universal Asynchronous Receiver Transmitter (UART). One
entirely satisfactory device I've used is a Giant AY-1013. This is
an old device and I don't know if they are still being manufactured.
If you can get one, it is easy to use in that it requires minimal
support (a clock and maybe a level converter for the serial line).

Hello all, I thought I would put in my 2 cents worth.
EASYTRAX is a cut down version of PROTEL AUTOTRAX which I use. The Laserjet
driver works fine with my HP Deskjet 540 printer. Alternatively you can
plot to a HP plotter and set the output device to a file, ie create a HPGL
plotter file. I have seen a few shareware programs which claim to print
these on a printer eg prtgl128.zip available by ftp
ftp.ee.ualberta.ca/pub/cookbook/softw/ibm/index.html - I havent used it, I
use a commercial program called PRINTIT which will also do the colour overlays.
Try exposing your PCB direct from a paper print - IT WORKS around double
exposure.
Regarding photo resists I have used ELECTROLUBE PRA200H for a number of
years with a mild caustic soda solution as developer. It works a treat, no
nasties in its use and exposes in sunlight or a Suntan lamp in 3-5 minutes,
not critical, I have forgotten some up to 25 minutes and still ok when
developed. Cost around AUST$35 for a 200mL spray can which lasts for years.

I can't tell you that, but I can tell you that I put a 75 ohm resistor
between ground and the antenna pad (as suggested in a book on Virtual
Reality I had). Up to that point I thought the xmitter was a peice of
s___. This little mod cleaned up the signal so well, it is better than the
local cable company's. I plan on making a filter for it some day, but I
don't know what freq to make it for. Anyone?

I had the same problems - Now I make all my through hole pads like donuts.
I etch-out a small hole in the center of the pad and this makes a perfect
starter. I usualy make this hole about 0.4mm and drill holes at 0.8mm
A small drill press in mandatory as are extra drills.

Thats All,
James

Hello all, I thought I might add my experiences making Photo PCB'S.
First,Easytrax is a shareware version of PROTEL's AUTOTRAX which has a laserjet driver which works fine with my HP DESKJET 540. Alternatively you can output a HPGL file to disk and use one of the many HPGL to printer programs. I use a commercial one called PRINTIT which allows printing of the colour overlays as well. Try your local BBS as I have seen many but didnt bother as PRINTIT did everything I needed.
I have had great success printing directly to PCB through the PAPER PRINT -- YEP! it works great, just increase exposure time around double.
I have used ELECTROLUBE PRA200H positive photo resist for years with great success.
I have 200ML spray cans which cost AUST$35 a can, although they do make a 100 mL can.
A little goes a long way so is not expensive. For developer I use a mild Caustic soda solution, about a level teaspoon to 1 Liter of water, no expensive developer needed although ELECTROLUBE sells on which doesn't work any better.
I hiope this is of some help, 73's from the mad homebrewer (both types)

I've seen 3.2 listed somewhere. I made my own measurements and
came up with a figure closer to 4.0

Since you'll probably need to tweak and tune anyway, those
figures should be close enough to get your design started.

I had been using a cheap commercial package called Easy-PC from an outfit called Number One Systems (hq in the UK with a representative in the SF Bay area). It only cost $100, but there were some bugs with it that made me send it back. I don't know if those bugs have been fixed, but it seemed as though it was an old program that was the design platform for their "professional" version at $400 and they just didn't want to do any more messing around with the cheap version. Just for grins, here are some of the deficiencies I've found. If anybody has later information that contradicts what I've written here, PLEASE leave a thread post so that everybody has the new info.

1. The manual did not document all of the commands. Instead of some sort of logical alphabetic or numerical reference to the commands, you got a twenty-page tutorial that takes you on the design of a "typical" board but doesn't give you a complete index as to where to find things. And, the tutorial wasn't complete in that it didn't use all of the commands. Oh, yes, there was a one-page matrix with all the commands listed, but not the syntax for the commands. On a $20 shareware program this kind of documentation is acceptable, but not on a $100 commercial package. And, the question is always in the back of my mind on a deal like this -- is the documentation on the rest of the programs from this outfit as abysmal as this one.

2. There was no "info" command. That is, if you wanted to know the thickness of a line on the board, there was no way to click on the line and have the program tell you that the line is .015" or .032" or whatever thickness the line really is. Ditto for pad sizes. Ditto for lettering heights.

3. The printed output (at least on the laser printer output, I didn't have a chance to check the Gerber output) would print diagonal lines thinner (30% ?) than orthogonal lines of the same design width.

4. The line edit command works on a "home node" "end node" basis without any apparent visual indication of which was which. You would go to erase one segment of line only to find that the erased segment was at the other corner of the board. God forbid that you err and lay down the same track twice from different ends of the board; you get into an infinite "erase" loop from which abandon hope all ye who err here.

5. It would be nice to have a couple of other colors than white, blue, and red. Yes, you can change these colors, but you have a total of three colors to work with.

6. You can't edit symbols per se. You can call the symbol in, modify it, manually erase the old symbol from memory, and then add the new symbol using the same name as the erased symbol. Only about ten commands to do what the clever program does with one.

7. The laser printer driver is extremely poorly behaved. It doesn't like even the generic Microsoft VGA driver loaded when it goes to work. Unfortunately, it doesn't just refuse to load. It loads and jams the system tight; not even ctrl-alt-del gets you out of it. Cold boot time.

8. Pads have "widths" or diameters numbered 1-16. Tracks have "widths" numbered 1-8. The only way to see what (for example) width #5 is is to go into the "user defaults" area and look it up. There is no way to print out this chart so you can paste it up over the computer to save time.

9. Each pad has a center hole definition that tells the drill program what size drill to use. You might suspect that changing the pad diameter or drill hole size on the user defaults for a layout would "globally" change all pads on the layout to the new diameter/hole. You would be wrong. You have to change each #$%@@**&S pad individually if you want the new diameters.

10. Ditto trace width. Even if the program wouldn't universally change a track width if you changed the user defaults, you'd expect one of the "block" commands to be able to change track widths within the block. You would be wrong. You change each and every #$%**&%$# line in the layout manually. God forbid you made the line out of two segments. You get to change each segment manually.

11. You can't keep drawings in a separate subdirectory from the symbol libraries. It all gets jumbled in together.

12. Rotating a drawing for 90° (laser landscape) output is a real trip. Even rotating an A-size (8° x 11) on the 17 x 17 "drawing area" requires geometry of the first kind and second order to keep from getting the dreaded "out of draughting area" error message. I tried it a dozen ways and it always meant moving the drawing to the center of the screen, rotating it through some jumble of math coordinates, and then moving it back to the target area. I never tried moving a B-size (11 x 17) on the 17 x 17 screen; I suspect I'd have a long grey beard by the time I figured out how to do it.

Anybody else tried this program? Any comments?

Assuming the gate is at ground as far is DC is concerned, it's easy. Deceide on the drain current Id, by checking on the data sheet what gives optimum performance. The best Id will depend on whether you want low-noise, or good strong signal performance. Now find from the data sheet what gate bias V will give this drain current. Then R=Id/V. If the gate is not at DC, you will have to make allowances. In practice, the required gate bias is not too well defined, so if the Id is critical, I would make the source resistor adjustable.

Hello...I am trying my hand at building a VLF (5 Khz) RF detector.
Because of the extremely long wavelength, an LC resonant circuit
takes LARGE values of either L or C. Does anyone have any suggestions?
Is there an easier way to do this? Might there be an amateur book on
the subject?

Thanks, Steve

I have an elegant solution to that problem.
Flow solder over the pad. The trick is to put enough down to form a doughnut of solder on the pad without it doming over the whole pad. The "doughnut" of solder acts as a guide for the bit and protects the pad. It's a lot easier if you flux up the copper first. I used to be a fan of brush on alcohol based flux but the water soluble flux pens & solder you get out of digi-key work great once you get the nack of it. They clean up easily too, no HAZMAT to worry about.

Indeed you were.

I use a paper base system at work to pump out quick and dirty proto
boards for testing before I release by stuff to the board house. The paper
doesn't shrink or warp as much as the plastic based stuff. Even with the paper
and a good press I'd say 5x7 inches is the limit for double sided boards
before registration errors get too bad. Good news SMT parts are now pretty
much standard, use them, no drilling! Use 1206 zero ohm resistors to
"jump" over a trace instead of a set of vias.

I'm trying to build an IF amplifier using JFETs. It's a common
source configuration with a parallel LC tuned circuit in the
drain circuit to VCC.

Naturally the source resistor goes to ground, but how do I calculate
its resistance?

I've seen how to calculate source and drain resistances but not
when there is a tuned circuit in the drain.

The resonant frequency of the LC circuit is 50MHz.

Any help would be most gratefully accepted, thanks.
Ian

An interesting question, would like to know myself. Could you assume that DC
ignors the tank circuit therefore all the DC bias, Vds, must come from the
source. If so then compute the resistance to provide the required drain
current. I donno, will be watching for an answer.

With most Mobile signals down several s-units from the home station antenna it hardly seems worthwhile to run qrp from the mobile. Unless of course you use the MFJ to feed a long wire once you camp. Then the Atlas will still be at least two s-units above the qrp rig. BTW I think the old Atlas is a pretty decent rig albeit simple. Sure was simple to fix too. I run a 210x in the car and don't worry too much about theft since I got it for 100 bucks at a flea market.

>simple receiver using 455KHz IF transformers and a standard FM demod
>chip from Motorola.

I like the idea of using a 455 kHz. carrier on the light, so I'll
complicate up the situation and ask for your considered opinion.

You have four kids, each sitting in a separate corner of the room.
Each of the kids needs to be able to talk to each of the other kids
either directly or through a "box" sitting in the center of the room.
You can't use the same frequency for each of the kids or you will get
capture effect on the strongest signal and/or heterodyning between the
slight difference in the vco center frequencies. Yet you can only get
cheap parts for 455 and a few kHz on either side, hardly enough
separation to put everybody on their own channel. Time share?
First-talk inhibitor on the rest of the receivers? The mind boggles
with the possibilities.

Your thoughts would be appreciated.

I think Wayne, WB7WHI, has the correct answer. The source resistance is computed on the basis of the desired bias point (or, equivalently, drain current) for the JFET, the tradeoff being noise figure vs. dynamic range. SInce the gate is grounded to dc, via a gate leak resistor or input transformer winding, the full bias voltage Vgs is developed across the source resistor. In my experience, Rs isn't critical, and it is best to fiddle with various values in order to find the optimum value. Rs is usually bypassed for r.f. so that gain isn't sacrificed.

Hi Gang,

I have all my PCB's made professionally, but occasionally I have to make a 'one off'. These can be made with the aid of a laser printer or photocopier. Using your CAD program draw out the circuit you require and flip it. So that you are looking at it from the component side. Print it on the laser printer, or if other printer, photocopy the result. This is because you want a thin plastic film such as these use. Place the laser print or copy on your PC board and wait for the wife to go shopping. Take the family iron and set it to its highest heat setting.

Wait a few minutes, and then iron the the print onto the board. The outline will be transferred to the board.

OK the edges will be a little rough, but the result will work providing the tracks are not too thin, or too close.

Then etch as usual.

Hello to all who read this message.

I am letting you all know that the Burnaby Radio communications WWW page is
now running stable, you should be able to check it out at any time.

Some of you had problems before accessing our WWW page, but that problem
should be over now. We have changed servers so our WWW Page should work all
the time now.

The page is at "http://www.burnabyradio.com/ham/brc.html"

We are: Burnaby Radio Communications Ltd.
4257 E. Hastings Street
Burnaby, B.C. Canada
V5C 2J5
Phone: (604)298-5444
Fax: (604)298-5455
BBS: (604)298-3283

WWW: http://www.burnabyradio.com/ham/brc.html

Please visit us!!!

And please fill out our form, and you will receive our latest price list.

Thanks.

I was under the impression that the 640 MHz is a from a SAW oscillator,
phase-locked to the 10 MHz in a very narrow loop. That way you get the
crystal noise characteristics (don't know what N is but whatever N is,
the noise is degraded by 20 log N) inside the LBW, and the good SAW
characteristics outside the LBW. The VCSO is better than any VCO you're
likely to build or find, if it's made from conventional resonators.

This isn't my area of "ex-spurt-tease", but the gold standard is a multiplied crystal, right? If you generate a comb into the microwave region from a good quiet source, you mix your microwave signal down to where you can measure it with a quieter source than the 8662 (which is pretty good, but not a Godsend). This is the approach that the 3048 test set uses, as well as the Comstron Phase noise test set, which I've only seen demos of. (I've used the 3048 long enough to have a love-hate relationship with it. Well...a tolerate-hate relationship).

If you can get the output frequency down below 1.5 GHz, the 8568 is a good spec. analyzer, apparently quieter than the 8566 (its big brother) You can measure noise directly on it, subject to the usual problems with measuring phase noise on a spec. an.. See the tons of HP sales literature/ap notes on this.

73,
Bob

5773. S parameters -> FET model

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-06 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995Dec6.165848.56886@ucl.ac.uk>
Source record: 109136

I've seen some posts recently reguarding the S-parameters of a FET at a low frequency. One method I've thought of to get these, without access to a vector network analyser (VNA) is to assume a reasonably decent model for the FET, having as a bare minimum the gate resistance Rg, input capacitance Cin, output resistance Ro, output capacitance Co, plus the feedback capacitance Cfb. It would be better to include also the parasistic components - ie package inductance etc.

Simple model of a High-frequency FET:

```
Gate-----------Rg------------ Cfb ---------------------------- Drain
| | |
Cin Ro Co
| | |
Source ------------------------------------------------------------
```

Then fit (non-linear least squares ???) the S-parameters at higher frequencies (from the data sheet) to the FET model, to get the physical values of the Rg, Cin, Ro, Co & Cfb. Once you know these, finding the S-parameters at any frequency would be trivual. Finding the optimum source impedance would also be possible - I think! Noise figure could not be estimated though.

Anyone ever managed to do this? I've read about it (Pengelly, Microwave MESFETS), but don't have any software myself, and feel it would take a decent while to write, but perhaps not too long. The book 'Numerical Recipes in C' by Press et al has fitting algoritms already coded.

Obviously measurements of S-parameters would always be better, but given few amateurs have access to a VNA, but many can write computer programs, this might be a useful method to estimate S-parameters at frequencies not on the data sheet, using the physics of the device, rather than extrapolation of the data sheet values, which is always risky.

One would have to guestimate the magnitude of S21, but all other S-paramters could be determined once the physical parameters of the FET are known.

Just as a side comment, the common gate configuration can offer
a pretty good input return loss in a 50 ohm system when using
a J310/U310. Might come in handy if you're using the IF amplifier
to terminate a diode mixer or a filter. Common source comes in
handy for terminating a crystal filter.

>Naturally the source resistor goes to ground, but how do I calculate

I've always used the same calculations to set the bias current for the
JFET regardless of the drain load.

Just choose a resistor that will give you one or two milliamps of
quiescent current. Then bypass it for 50 MHz. You will probably find
a value in the range of 100 to 1000 ohms will do the trick.

Glenn,
You need to understand that RF resistors cannot be wire-wound!
They exhibit too much inductance! You will need special power resistors
to make a good attenuator. It is non-trivial to build a good RF
attenuator, thats why they cost so much!

Tom

At HF the 8662 is maybe 30 dB. better than a good spectrum analyzer like
an HP 3585. Most crystal oscillators are better than the 8662, and
most VCO's are noisy enough to be seen on the 3585. So relatively
few sources fall into the 8662 niche.

>use synthesized LOs. Are these better than high performance HF oscillators?

In some cases, yes.

>How do you measure phase with a spectrum analyzer? How do you achieve the

You can't measure "phase" with a spectrum analyzer. You can
however measure *phase noise* with a spectrum analyzer by looking
at the noise sidebands.

>required dynamic range with a spectrum analyzer. This info would be very

Use a wide enough resolution bandwidth so that the noise is less than
100 dB. down.

>useful to me.
>
>73, Wes

Regarding modulation domain analyzers (MDA): you have to supply a clean
10 MHz reference to them (or use the optional built in 10811 timebase).
There is no need for a variable signal generator with MDA techniques.
In some cases, you want to beat the signal down to less than 1 MHz.
A crystal oscillator with a crystal socket and a dozen or so crystals
will take care of this. You get more resolution by down converting.

MDA boxes are ideal for close in phase noise where other techniques
fall apart.

I've seen it published at 4.7 and 4.8, The only problems with
using G10 is that it is rather lossy at microwave frequencies
and also the dielectric constant is NOT a controlled parameter
of the material, so it may vary from batch to batch. I've had
good results at 1.3Ghz with it though.

I need a 4864 kHz xtal, and I have one that's 4915.2 kHz. My calculator says that that's a difference of a little more than one percent. I've been filing on the case to try to get it to come apart without messing up the rock. I'm gonna try the old pencil lead trick on it to see what happens (like I'm only wasting $.49 if I ruin it). So what is the usual or maximum amount of freq shift a good deposit of pencil lead will cause? Any ideas?

Glenn,
You should use either carbon film, carbon composition or perhaps in the
low values you require, metal film. You don't mention the frequency range of
your transceiver but I assume it's HF or VHF so axial leads will be OK
if kept short.

Because you want to use a pi, the nearest standard values are 300 ohm for the
shunt and 18 for the series. You will obviously be dissipating 5 watts, so the
power ratings should be capabile of handling this. I would suggest using parallel
combinations of lower wattage resistors. If you use good construction techniques,
you can obtain a reasonable SWR into the low VHF region. If you don't mind
dissymmetry, you can use lower wattage parts on the output side.

Good luck and 73,

hello brian,

the harris HD6402 is what you need. Its easier to use than the
common AY devices. Baudrate is externally generated. The IC is
a serial/parallel converter and vice versa. Baudrates are up to
100kBaud. I use it to serialize the AD converter output of my meteosat
converter.

Try http://www.semi.harris.com to get a datasheet. The fax infothek
really works wordwide!

If you have futher questions drop me a note!

Practically none of the 'non CPU' UART chips that were so common in the 70s
and early 80s are available anymore. You can get the same results with
many microcontrollers now, but that requires investment in tools and
programming hardware.

The easiest would be to buy a ready-made RS232 to centronics converter,
the way most favoured with the sci.electronics group would have to
be using a microcontroller. Cheap too if you're not counting the hours.

Not quite the response that you expect, but the Radio Ham Handbooks from
40 years ago describe such techniques.

Also, when using a VXCO circuit, you can usually reckon on a stable
shift of 1kHz per MHz. eg, on the 144MHz band, before the days of
the modersn synthesized approaches, you could reckon on swinging
a two-metre transmitter about 150kHz.

You might consider the idea of plugging 2 meter H-Ts into transverters.

The July 1991 QST has a design that uses etched filters. Its reprinted
in the ARRL UHF/Microwave Projects Manual. If you need more than 20 mW,
it isn't too challenging to hook up a hybrid power module that will
boost the 20 mW to 10 or 15 watts. A minor problem is the LO, it isn't
designed for precise frequency netting. One approach is to use an HF
VXO and multiplier. The use of two LOs can solve the problem of the
repeater offset, if the radio can't handle it.

Zack KH6CP/1 I've used helical filters to make a 903 transverter
zlau@arrl.org (4 dB NF/20 mW out) the size of a block of butter.

I humbly suggest that 455 KHz is the wrong frequency to choose unless you are going to use FM. 550 KHz is just as easy to do and then you can use a $7 pocket radio from radio shack to do the IF. You can't even get a box to put it in for $7. They have something called a flavor radio for $6.99 in the 1994 catalog. You could use a AM signal to modulate the beam and send the AM from the photo detector into the antenna of the radio.

On the subject of 4 kids in the same room:

You can do it cheap or you can do it full duplex.

The cheap way simply has everyone listen on the same frequency and only allow one person to transmit at a time. If 2 people transmit at the same time nobody hears anyone else, but we have this now in a lot of communications systems.

One full duplex way is to have 3 receivers on different frequencies for each child and combine the audio from each receiver into one headset.

Another full duplex way is what was suggested earlier. It requires 5 receivers and 5 transmitters for 4 children. Each child transmits on a unique frequency to a central repeater. The central repeater has a receiver for each child's frequency and combines all 4 signals into one audio signal that is transmitted on a 5th frequency to all children.

I hope these ideas help.

From: kferguson@aquilagroup.com
Message-ID: <4a7b8h$g3t@mack.rt66.com>
Source record: 109160

Please, could we NOT turn this thread into a debate over the value of QRP operation?

I would also like to know about these rigs (the 20M in particularf).

I am a sailplane pilot..In the winter it is sometimes possible to "park" at 20,00' MSL or higher (Yes, we have O2, and an agreement with ATC...100% safe...and even legal!)

I often dream of the DX that should be possible ...Higher than most mountain tops, and MILES from the nearest powerline,ignition system, or other source of interferance!

I like CW fine, but SSB will be far less distracting, thus safer. Some may be able to copy CW and fly OK, but I know MY limitations, so have perished the thought of using my HW-8 in glider..

I have very limited power available from gell-cells, (especially as temperatures are quite low) and very little room in cockpit. (I'm 6'5", cockpit is not!). Also, the rig must not swamp AC band VHF reciever. MFJ rig looks like the ticket..small, low power, few controls to distract me......

A zepp (almost what it was designed for, after all!) at 20K' MSL should produce a fair signal, QRP or not.

So could we please hear from someone who has USED one of these rigs, or other (ten-tec??) QRP ssb rigs?

In anticipation of flames: I think homebrew group is a likely place to look for QRP operators, so, while this is not a hombrew thread, it IS probably the best place to post such a quiry.

> Any ideas?

Most modern crystals have plated electrodes. The pencil lead
trick was good for the old slabs of quartz that were held in between
copper plates with spring pressure. You will likely break a modern thin
crystal by trying to use a pencil on it.

If you could get ahold of sonething to do some electroplating
with, you could tie both pins together and plate a little more electrode
material thickness onto whatever's there now. There's also some
"electroless" tin plating solutions made for pcboard fabrication that
lays down a tin plating just by dipping the stuff in it. No batteries
needed.

5804. Help Needed: Expert Hackers only (long)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-07 00:00:00 UTC
From: pfzouave@aol.com
Message-ID: <4a799h$qfv@newsbf02.news.aol.com>
Source record: 109165

I am in the process of developing a tiny computer controlled medical monitoring device. The device, only a few inches square, is intended to be located at the patient's chest, at the sternum, and held in place there by a bra-like attachment garment. The garment features a pocket or holster in which the monitor is placed.

While the system in fact works, the practical success of the device hinges on the ability of the unit to detect whether or not it has been has been removed from the patient. I call this "tamper protection."
To date, I have been unable come up with a tamper protection scheme that meets the necessary engineering criterion. The circuitry must enable the monitor to tell whether or not it has been removed from the patient's body. The added circuitry must be cheap, as simple as possible, and utilize a few active components as possible(the device is battery-powered, so power consumption is always an issue.) It must not be easily defeated, and must function at varying battery voltages down to, say, 3 volts. Ideally, such circuitry should function properly from the moment of assembly, that is to say, it should not require tweaking or calibration. While the computer used in this project has limited analog input capability, the ideal tamper sensing scheme can warn of a tamper condition with a single binary bit.

The first idea for tamper protection involved a magnetic reed switch or hall effect sensor. A magnet was to be stitched into the garment or apparatus fixing the unit to the patients body. If the monitor was placed in the garment, the magnet would be in proximity to the sensor, and the computer would "know" it was on the patient. If the monitor was removed from the garment, the magnet would no longer stimulate the switch, and the the computer could conclude it had been removed. This scheme was attractive for low parts count, simple binary connection to the computer, and low power consumption. Unfortunately, there is no electronic means to detect that the *garment* is on the patient. Thus, the system is easily defeated by placing the monitor in its attachment garment, but simply leaving the garment on a table or chair.

The next idea was optical. An aperature and photo eye would be installed on the backside of the monitor. As long as the monitor was in place on the patient, their skin would block ambient light from reaching the monitor's photoeye. If the unit were removed, ambient light would fall upon the photo eye and the computer would conclude the monitor was no longer on the patient. Like the magnet scheme, the interface to the computer was binary, and both power consumption and parts count for the support circuitry was low. But, like the magnet, this scheme was easily defeated. The system cannot differentiate between light occluded by human chest or a table top. Worse yet, a piece of adhesive tape over the eye disables the system

entirely.

An obvious parameter upon which to base tamper protection is temperature. Living beings radiate heat. Surely a temperature sensor mounted in the monitor could detect this, and distinguish between a warm body and a cool tabletop. In theory, this is true. In reality, the scheme is not practical for very subtle reasons.

When the temperature scheme was first concieved, certain assumptions were made. It was assumed that a nominal value for ambient air would be 75 degrees F. It was further assumed that body temperature was 98 degrees F. This suggested a temperature span of over 20 degrees between the condition where the monitor was lying on a table, and the condition where the monitor was affixed to the patient's chest. Therefore, an arbitrary threshold of 85 degrees was chosen. If the measured temperature was below 85 degrees, the computer was to conclude that it was not attached to the patient. If the measured temperature was above 85, then the monitor was assumed to be in place on the patient.

The problem is that body skin temperature may is significantly lower than body core temperature. As an example of a reasonably healthy adult, my sternum skin temperature did not exceed 90 degrees. In the case of sick, elderly patients, who may well be suffering circulatory problems, their sternum skin temperature is likely to be even lower. If the temperature sensor is mounted inside of the monitor case, or is mounted on the face of the case but the case is not in good contact with the patient's body, the measured temperature will be even lower.

Nor can room temperature be assumed to be any particular value. It is not inconcievable that in a facility caring for sick non-ambulatory individuals, room temperature may be raised to provide additional comfort. Thus, the possibility of raised room temperatures and the probability of reduced body temperature values diminishes the temperature span between the monitor-on-patient and monitor-off-patient conditions, and makes it more difficult for the computer to discriminate.

Add to this significant problem these other concerns: Mass produced thermistors may vary from unit to unit in their electrical characteristics. This variance can be up to 20%. Assuming the temperature detection scheme can even be made to work, at the very least it would require careful manual calibration of every monitor unit produced. Secondly, the output of the temperature sensing scheme is not a convenient binary state, but an analog value. This requires use of a power-hungry analog port on the computer. The computer's analog resolution is limited to 8 bits. Active components are necessary to scale and offset the temperature signal, which comes at the expense of battery life and circuit board real-estate.

I entertained building a tamper system based on some common "touch switch" type circuits. The idea was to fit a small metal plate or pad to the rear of the monitor. When the monitor was in contact with the patient's skin, it would be activated. When the monitor was removed and placed on a table,

the sensor would be deactivated. This was an appealing sensor because its output was binary in nature and it seemed that such circuitry could be made to work at low battery voltages. The method of its operation would not be intuitively obvious, which would enhance its resistance to being defeated.

The problem with this idea is that virtually all the circuits I have seen to implement touch sensitivity depend on the induction of stray 60Hz into the sensor pad. When the sensor electronics are coupled to the AC power or ground (even through a transformer and DC supply), they can be made extremely sensitive and reliable. In a battery powered application like this one, the electronics "float" with respect to earth ground, and these touch sensing schemes no longer work properly.

Unwilling to give up the concept entirely, I prototyped a touch sensitive circuit that does not depend on 60 cycle noise. It features an oscillator that generates its own excitation signal. The presence or absence of a body in contact with a sensor plate is judged based on the body's effect on the excitation signal.

The circuit is built around the 4049 hex inverter. Inverters a, b, and c comprise a text-book square wave oscillator running at around 100kHz. The 100KHz signal is then fed to a sensor pad.

The pad consists of 2 sided copper clad board, and is about 3/4" square. The front of the sensor is solid copper. The rear is actually divided into two equal rectangular pads, each half the size of the pad on the front of the sensor. The square wave signal is fed directed into on of the rear pads. The signal is capacitance coupled to the front pad, and from there, capacitance coupled back to the second rear pad. (Electrically, the arrangement is like two disk capacitors in series, where the 100kHz signal is fed in at one end, and exits the other. The touch pad is the terminal in the middle.)

The signal exiting the sensor is amplified by inverter d, which is biased with a trimpot to operate in a linear mode. The output of the amplifier is fed through a diode, and charges a parallel resistor capacitor pair (the three of which form a demodulator of sorts.) Finally, the signal is buffered by and inverter e. For test purposes, a common LED is connected to the output to show the state of the system. The system as a whole operates as follows:

The 100kHz signal couples through the sensor, through the amp, and through the demodulator. The capacitor/resistor pair are charged to a positive value, which the final inverter converts to a "0", thereby causing the LED to remain dark.

If a finger is applied to front of the sensor, the conductive body mass causes the 100kHz signal to be bled away. It is *not* coupled to the recovery amplifier, so no signal is forwarded to the parallel capacitor/resistor. Eventually, the charge on the capacitor bleeds to 0, which causes the final inverter to light up the LED.

Summary: If you touch the sensor pad, the LED comes on. If you don't touch the pad, the LED goes off. Yes, the system actually works, and on only 3 volts. Its nice because it involves only one IC, and a few passive components. Still, the design does not meet my minimun requirements.

Why? Because the recovery amplifier is a linearly biased inverter! The bias value is tricky, so a trimpot must be included in the design. Besides consuming space, trimpots are unacceptable in this design because they require that every single unit produced be hand-calibrated. Worse yet, a calibration for one operating voltage fails to work at another. If I calibrate the system to work at 4.5 volts, it will not work at 3 volts, and vice versa. In a battery operated design where supply voltage may well fluctuate, this is unacceptable.

I have tried to implement the same sort of design with other 3 volt IC's like the LM324 quad op-amp, for example. That attempt failed because I could not induce the op amp to oscillate at 100kHz. An LM339 quad comparator makes an outstanding 100kHz source, but I cant seem to get it to function as a recovery amplifier.

So, I come to the final point: Do any of you hackers have a solution to this vexing problem? Are there any circuits, chips, or components you can recommend? Perhaps the solution is to emply some entirely different tamper sensing scheme, maybe based on patient heartbeat or respiration?

Email pfzouave@aol.com. Any assistance is greatly appreciated, because Im stuck.

I bought CIRCAD a year ago for $300. Not bad for the price. It has full schematic capture and layout capabilies, but minimal libraries. I use high buck stuff now that I do it for a living but I still find it useful for the quick and dirty hobby scale projects though. A demo version is available on mobius as I recall. Their BBS is 305-584-7089. Prints to my HP500C nicely. I just photocopy my output to transfer paper for layout.

That was a rhetorical question. How do you separate the phase noise
sidebands from the AM sidebands without phase detection?

>>required dynamic range with a spectrum analyzer.

>Use a wide enough resolution bandwidth so that the noise is less than
>100 dB. down.

What do I do when my spec gives me a number at 100 Hz offset and a different
number at 1 KHz offset...etc, and I need a 10 Hz BW to do this. Or, sometimes the
phase "noise" isn't noise at all but discrete sidebands which have to be
resolved.

>Regarding modulation domain analyzers (MDA): you have to supply a clean

>will take care of this. You get more resolution by down converting.

Well, we've gotten quite far afield from the ham biz, but since we're here, as an engineer, I would love to build these goodies. However, at least where I work, our test equipment is usually racked and stacked COTS (latest buzzword). So, we open up the HP catalog and keep you employed :-)

>MDA boxes are ideal for close in phase noise where other techniques
>fall apart.

I'm not real familiar with these, however, don't they just measure total SSB noise and not "phase" noise. While this is usually the dominant source, we do have requirements to separate AM & PM.

I have heard rumors that the police radar gun itself will detect
some radar detector's local oscillator. A well made detector such
as the one you describe should be invisible to the radar gun.

>
> Jim
>

Interesting problem, I didn't remember the original posting. But the simplest solution is to treat the channel like a 2M simplex channel. Everyone hears everyone else, and they learn to talk one at a time.

If that is too simple, maybe PL tone squelching could be added. Add a sub-audible tone to the transmitter. If a different tone is used for each kid, the person transmitting selects the tone for the person that he wants to talk to. To prevent capture effect from someone else transmitting at the same time, each transmitter could be inhibited when the receiver sees a signal (other than its own).

It might also be possible to pull the frequency of the if transformers enough to create two channels, and build a repeater in the center of the room. Everyone transmits on one channel (maybe 430KHz), the repeater retransmits on the second channel (maybe 465KHz) for everyones receiver.

Last thought (today at least)... Just looking through the newest Ramsey catalog (just came yesterday), and they have a simple IR voice link kit. I think that it is an AM system using 30KHz carrier. I haven't had much experience with Ramsey kits. THey don't look like Heathkits, (look cheaper - and the one kit that I did see had somewhat confusing instructions), but should be workable.

I'll give it some more thought, and maybe see what some of the
others on the group come up with......

I'm about to do the Chipswitch mod to my HR2600, and I noticed a six pole DIP switch marked 'S301'. Mine currently has switches 1,2,5 and 6 OFF, 3 and 4 ON.
Anybody know what these switches do, and if they have a function with the Chipswitch uProc?

Anybody want an old UC-1251 uProc? ;-)

Galen, KF0YJ

I'm using my 2600 as an IF for transverters.

>
>Tom

And you need to understand just because a resistor is metal film, carbon,
or labeled non-inductive it may not necessarily be so in real life.

Nearly ALL carbon and metal film resistors have elements wound in a
spiral, and the higher power resistors "fall apart" in the upper HF
region. This is a huge problem in parasitic supressor design, and
applications like yours.

You can cut the resistor open and look at the element, or measure it on a
SWR analyzer to verify the quality of the component.

Most companies order special resistors for RF load and attenuator
applications. You will be better off using an array of small resistors, or
ordering special components, than randomly using 2 or 5 watt components.
The larger the component, the more likely it is you will run into this
problem.

Cross-posted to: sci.electronics,rec.radio.amateur.homebrew

Time to throw a question "over the wall" as I've not been able to locate a cost-effective, secure solution.

What I'm seeking is basically a short-range DC transmitter/receiver pair that functions much like a garage door or gate opener (and in fact it is the latter for which the pair will be used) that offers a fairly-high level of security. Note that 12VDC is all that's available to the receiver, as the gear-motor driven gate is in a remote location (powered by lead-acid batteries charged by solar panels).

The best thing I've found so far is certainly cost-effective but has only 2^8 combinations and thus isn't very secure. Anybody got sources for anything better or schematics or references? (I'm a physicist -- not an EE, so while I could ultimately [perhaps with great wailing & gnashing of teeth] design something that would probably work, I'd much prefer something _known_ to work!!!)

Thanks for any light anyone would care to shed on the subject

Richard

Many of these devices operate on a "low-voltage" AC source. Typically, in the garage door opener, there is a transformer. The secondary of this transformer is in series with a relay which controls the opener, and in series with this is the receiver unit. The receiver unit is connected to the opener by a pair of low-voltage wires. Not all of them work this way but a lot of them do.

In the receiver, the AC is rectified to a DC supply which powers the receiver. When the appropriate signal is detected, the receiver "shorts" itself out for a few tenths of a second. This triggers the relay in the door opener. There is a relay (either mechanical or solid-state) in the receiver which shorts the terminals together. While the receiver is "shorted", it runs off of some internal filter capacitor for the brief interval.

In this arrangement, you **might** be able to get the thing to work off a pure DC supply. What you would need is a schematic of the circuit and be able to understand how it works. Perhaps some modifications might be needed, such as removing rectifier diodes, adding a regulator, etc. You might or might not be interested in doing this.

Also, I do not think that 2^8 combinations is particularly un-secure. Remember that the potential intruder would have to not only try all 256 codes but learn several other details such as frequency, encoding method, etc. All of which make their job much more difficult. If it were me , I would stick with what you know can get to work.

The dielectric constant of ordinary green PCB is between 3.9 and 4.3, your
measurements were good. It varies depending on the ratio of fiberglass to
epoxy (I think they put in more of whichever is cheaper that day!).

> Since you'll probably need to tweak and tune anyway, those
>figures should be close enough to get your design started.

should be close enough to get you started. you don't want to use it for
too high in the microwaves, anyway. I recall measuring about 0.75 dB for
a 3 dB branch line hybrid at 2304 MHz.

Source record: 109038

Seems to me the simplest and most effective way to do this is use the "garment". Most bra's fasten at the back with a couple of little metal hooks. Seems like it would be easy to sew into each side of the garment a little braided (for flexibility) wire which connects to its associated hook in the back. Around in front, the two wires go into a miniature two pin plug. The plug's mate is in the patient monitor device. One pin has a pullup resistor (100 kohm or so) to 3 volts and to the logic sensing input. The other side is connected to ground. If the input ever goes high, you know the monitor was pulled out, or the garment strap was unhooked... Interesting application. Hope this helps

Expert Hacker?? ..... Oxymoron :-).

I have no experiance with "touch sensorsd, exept as RFI generators
:(.
If this approach does not pan out, here are some alternatives you may
not have considered.

Idea 1:

I saw a device once, used to automatically forward phone calls to the
room where a person actually was. (eg. a doctor making his hospital
rounds) This required them to wear a IR tag....but if they took the
tag off, and left it on a desk, they wanted the tag realize it was no
longer attached to the person.

They used a sensor that was a can with a metal ball in it. It had
several contacts that the ball would short togethor as it rolled
around in the can....It was a motion sensor in other words. I think I
have seen these sensors for sale in electronic trade magazines.

This would probably work unless your patient is paralyxed or comatose.
Even when asleep, people move around every so often. I guess it could
be defeated by putting it on an oscillating fan or something like
that. There would have to be a pretty long delay before removal was
detected...maybe you can't live with that.

Idea 2:

I do not know how it worked, but in Isrial I saw device attached to a
infant's crib which detected if the child stopped breathing (SIDS) and
sounded an alarm. It had an antenna under the mattress. Perhaps the
principle of operation could be applied to your device. I have not
seen or heard of such device in this country..but then I don't read
parenting magazines etc. Perhaps this is common device here too, or
maybe you could search for info on it (sounds like you may be in a
related business)..Sorry I didn't note the brand name (I don't read
Hebrew!) or any other info to aid your search.

It was sensitive tothe breathing of a sleeping infant...so even
elderly ofr infirm patients shold not present a problem.

Idea3:

You already have the brassier like harness...you could apply
sphygnanometer (sp????) principle: A crude strain gauge could measure
the tension in the "around the chest" strap, and see if it had an AC
component (breathing). This would take quite a bit of Rube Goldberg

work to defeat.

I use PnP Blue for prototyping at work. First, clean your boards with Hydrocloric acid. This
might be toilet cleaner. That helps the stuff stick. Second, use a small punch to lightly
mark your holes. I also use the Dremel. Use high quality carbide PCB drills. For an iron,
I use a iron used for ironing monocoat onto model airplanes. Seems ready made for the work.

Hope this helps!

Source record: 109041

I guess what is needed is to change AC into DC and measure or monitor the DC changes over time. Also, some selectivity is useful; this seems to be the key problem in the inquiry. Well, L-C circuits have been used forever in RTTY demodulators for selectivity. Nowadays, they are often replaced or enhanced with electronic filters, either op-amp or DSP filters. These are available in many forms from lots of sources. MFJ makes cheap but functional filters-- look at their 784b: specs too numerous to list, but "tunable 'brick wall' bandpass, lowpass, highpass, notch, ... programmable pre-set filters, automatic multiple notch filter ... adaptive noise reduction...." Lists at $239.95, less at radio stores. Unfortunately, top-freq. seems to be slightly less than 5KHz as delivered, but quite possibly MFJ will reprogram the DSP rom to up the top limit to over 5KHz if the processor is fast enough. This seems likely because it does alot of work besides filtering if you require. JPL systems makes the

NIR-12 which is not as "knobby" as MFJ but probably much more powerful (dual DSP chips, rs-232 control, and they will custom-program your roms for freq. at the time of order or for $35. thereafter. Use a not-too-long antenna (lowfer hobbyists use (and sell) ELF receivers using extendable whips of about one meter coupled into an fet impedance matcher and a simple half-wave diode detector to your AF amp and earphone. With this I can receive Omega and hear a car pass by on a street from 30 feet. It sounds like a hissing noise. When I walk on grass it sounds like a microphone is strapped to my shoes, but again it is ELF electrostatic or 'rf'. The only selectivity on this receiver is my ear's frequency response. I guess it depends on how critical your requirements are as to how much sensitivty, selectivity, and immunity you put into a design. I'm glancing at an older book Sams 'Analog Electronics for Microcomputer Systems'. It has a summary of transducers: mechanical, fluid, radiation. You could use piezioelectric or magnetoresistive. Think of a giant tuning fork at 5KHz coupled to a detector by a coil. Collins mechanical filters are something like this. Well, this could go on and on. Finally, consider one of the commercial do-everything ELF through HF receivers that come up for sale from time to time. I bought a surplus receiver with selectable xtal filters tuning down to I think three KHz before it gets lost in autodyne (self-reception), and up to about 1 MHz. It is hybrid tube/transistor (about 1970 design?) and I paid $150 shipped. If it were shortwave, it would be of rather high quality compared to most. Check the net and surplus dealers for this kind of equipment.
Good luck. Jim K9ZAT

It's worth mentioning that around here, at least, there are people who
specialize in this type of burglary and apparently they're pretty good
at it -- we had a special on the news not too long ago about how easy
it was to break into houses with garage door openers. I suspect that
most of the job nowadays is in the form of hardware you can buy from
people who sell shady quasi-legal stuff like this (nominally for
educational purposes only, of course, just like 1kW CB linears etc.)
so better not count on store-bought stuff for Fort Knox security ...

The Apollo 16 mission (I think) left behind an array of scientific instruments on the moon which transmitted telemetry somewhere near 2.8GHz. I think it was shut off a long time ago due to lack of funding to analyze the data.

>likely to build or find, if it's made from conventional resonators.

I can see why you would think that, but actually, the SAW resonator in the
11729 is used as a crystal filter to clean up the noise floor of the
multiplied up xtal osc. So the xtal/multiplie is responsible for good
phase noise out to about 1 kHz. from the carrier and the SAW filter is
responsible for rolling off the noise farther away. There is a utility
mode of the 11729 where you can connect the output of the SAW filter
module back to the input and make it oscillate at 640 MHz., but that
is rarely used, for good reason.

BTW, I used that same 11729 SAW resonator to make a phase locked 640 MHz. SAW
oscillator that was used in the HP 5071 cesium clock. But I didn't
get as good phase noise as the 8662/11729 system, although it was good
enough for its application. I recently redesigned that module to be
a multiplied up crystal oscillator as in the 8662, although I didn't
need the extra 80 MHz. crystal filters, since my requirements were some
what laxer than the 3048 guys. Nevertheless, I picked up some improvement
in phase noise compared to the old PLL-osc. configuration.

>noise test set, which I've only seen demos of. (I've used the 3048 long enough
>to have a love-hate relationship with it. Well...a tolerate-hate relationship).

If you are not entirely happy with the 3048, you might want to look at HP's
modulation domain analyzers (MDA) for measuring phase noise.

The gold standard is a multiplied crystal where the multipliers have narrow band
pass filters to clean up the noise floor. As has been previously mentioned,
the 8662 has filtering at 80 MHz. and, I think, another frequency to do this.
Then there is the SAW filtering. BTW, HP's Santa Rosa people have developed
a "STW" resonator that is supposed to be even better than SAW.

5834. RF circuit simulator choice?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-08 00:00:00 UTC
From: peterw@dyson.BRisnet.ORG.AU
Message-ID: <199512082016.GAA24740@dyson.brisnet.org.au>
Source record: 109047

Hello all, I am having a great dilemma in finding a good (and RELATIVELY cheap) circuit simulation program for my RF (VHF to MICROWAVES) circuits. I have been using CALTECH'S PUFF which works OK but has a few too many liberties when analysing Microstrip circuits, particularly coupled filters. For low freq. work, I find MICROCAP (student edition) terrific but it doesn't do transmission lines. I downloaded APLAC but the 14 MEGA bytes of docs are horrendous, and are not easy to follow (very disjointed). The best I have seen and used would be ARRL's RADIO DESIGNER but it does not support transmissio/microstrip lines (A big mistake I feel as the rest is great and the price is good at AUST$300) So far my best choice would be EAGLEWARE's SUPERSTAR but at AUST$1500 + 50% import duty way out of an experimenters pocket. Any suggestions???
Does anyone have a earlier version of SUPERSTAR for sale that would fill my needs ?? NO I AM NOT SUGGESTING YOU STEAL A COPY!!!!. I believe in fair payment for good original software.
Back to you --- Best for Christmas Peter VK4AWP.

The radio shack PC material is very lossy at VHF and higher. I don't precisely remember the dielectric constant but it forces very tiny striplines. For anything above VHF you should find a supplier of a Glass / Teflon material. It's a little expensive but will give superior results and striplines that are big enough to be accurate.

From: elendir@enst.fr
Message-ID: <4a9544$cbv@tempo.univ-lyon1.fr>
Source record: 109049

Hi,
yet another question :-)

This time, I got a question about the design of a 23 cm (1291 MHz)
cavity. It is supposed to be used for a repeater to be installed in Paris.
It would be part of the duplexer.
I planned to obtain -120 dB at 1297 while maintening -3 dB at 1291
(insertion loss).
I just wonder if anyone has already done this kind of design. If yes :

- What are the size of the cavity (assuming it is a cylinder)
- What is the material (Brass, silvered brass, copper).
- How is it coupled to the antenna
- What is the Q
- How is the tuning system
- How much did it cost !

I just figured out that for a TE111 mode cavity, a diameter of 136 mm
was a minimum. Made in copper, it yielded Q~30000.
What about coaxial cavity ? It seems more compact but much less
selective.

Thanks for any info !

I have used the same resistors with good result.

Recently I have been using Cardwell prower resistors. They are made in
a TO3 or TO5 package and according to Cardwel they are flat to over
100 MHZ. I used 2 50 watter 100 ohms in parallel with a UHF conector.
With not too careful construction it's flat on two meters and has a
two to one SWR on 440.

Allide radio stocks them.

Good point. Of course you can't separate AM from PM noise with a
spectrum analyzer. In the vast majority of cases, PM noise dominates
and/or AM noise doesn't matter much, so the spectrum analyzer gets
the job done.

If you have to measure the AM noise, you're probably stuck with
a 3048 type architecture.

>>>required dynamic range with a spectrum analyzer.

>resolved.

What I use in my home lab (we have a 3048 at work) is a W-G TSA-1 spectrum
analyzer with 1 Hz. resolution BW. It gets in pretty close. Probably
closer than you would ever need for ham radio work.

>>MDA boxes are ideal for close in phase noise where other techniques
>>fall apart.
>
>I'm not real familiar with these, however, don't they just measure

>dominant source, we do have requirements to separate AM & PM.

Unfortunately, many people are still not real familiar with
MDA boxes. But when they learn about them, they often find them
extremely useful.

Spectrum analyzers measure total SSB noise and not just phase noise.
MDA boxes measure phase noise only and don't respond to AM noise.

You're in trouble here. The only way to truly know what they are is go to the equipment manufacturer for the spec. In most cases, the device manufacturer was contracted to mark the devices with the special part number and is prohibited from disclosing exactly the specs and consequently the device type. Otherwise, you must guess from the application and compare with data books from the device manufacturer. That kind of package is available from Motorola, Philips, NEC, and almost everyone else that builds RF devices.

The old TS520 and most early rigs with transistor front ends and mixers were a bit soft in the front end. If you were corageous, you could modify it. Lots of articles in QST by Rhode and others.
If the offending signal is local (say another ham up the block) a "null steerer" can help. See QST 1995 or JPS electronics model ANC4 will work too.
Most new rigs are better with the TenTec Omni VI being the best in my opinion.
Modifying the mixer in the TS520 may be the most effective was to improve your overload problems.

Actually, most microwave ovens operate at 2450MHz (right at the top of our ham band).

Use an audio amplifier to power a lightbulb from an audio source. Connect a photocell to the input of another audio amplifer and speaker. The audio from the first amplifier will make the lightbulb flash and the second amplifier will reproduce the modulation of the light "carrier".

our
> ham band).

More like all over the band. The signal is about 25 MHz wide. If it's any consolation, it's only on half of the time. The power supply in the oven is a half-wave voltage doubler, so the magnetron doesn't operate during one half-cycle of the power line. This varying, unfiltered power causes the mangetron frequency to FM all over the place though. In very limited research (sample size of 2), the ERP from a typical closed, apparently properly maintained oven was about 1 Watt peak. Doesn't look like the commercial communication interests are going to want to take over *that* band anytime soon!

As I understand it, the frequency chosen doesn't have to have anything to do with resonance of water molecules. It's the current induced by the waves due to resistance and/or dielectric loss in the food or drink that cause the heating effect. For example, the metallized lining in a microwave popcorn bag will absorb the microwave energy and heat up the fat inside the bag, which transfers heat to the corn to pop it. No water is involved other than that in the corn kernels, and that is heated indirectly.

[...]

The rest of the system presumably measures some biological phenomena (being strapped to the chest, it could detect heart and respiratory activity easily). Of course if it is removed, these readings would go to zero. Presumably the sensor is to determine if a zero reading is because the patient's vital systems are in distress, or if the monitoring device has just been removed. Other uses could be to prevent/discourage theft or misuse, or to place the monitor in a low power state when not attached to a patient and therefore not in use. Or there may be more sinister application?

Kevin's idea about a motion-detecting switch is a good one. If it's to distinguish impending death from a false alarm, it may be too slow.

If two electrodes can be in contact with the patient, simply detecting the resistance between them could work. A reading of infinity means monitor is not attached, slightly more advanced circuitry could also detect near-zero reistance that would result from attempting to defeat the sensor with a metal object. Detecting the resistance could be with comparators, an analog input, or a RC oscillator the frequency of which is counted by the

digital circuitry.

One electrode near or touching the patient could be used as a capacitive sensor. Most of these are base on oscillators with less than the usual amount of feedback so they stop oscillating if a body is near the sensor plate (which is connected at or near the input of the oscillator). This is easy if the sensor plate is actually in contact, the change is much more subtle if it is only capacitively coupled. I believe the "stud sensor" used for locating wooden wall studs works on this principle. But it has to be constantly adjusted by the user. The Israeli baby-monitor probably works on a differential principle as well (AC-coupled amplifier to detect small changes caused by the baby breathing or moving), so it's really a variaton of the motion switch concept rather than an actual body detector.

>Why? Because the recovery amplifier is a linearly biased inverter! The
>bias value is tricky, so a trimpot must be included in the design. Besides
>consuming space, trimpots are unacceptable in this design because they
>require that every single unit produced be hand-calibrated.

As an aside, CMOS inverters can be biased into linear operation (with no tricky adjustment), with simply a resistor from the output back to input. It is a good approximation to model the inverter as an op-amp with the non-inverting input internally tied to half the supply voltage (a very common configuration). The gain of the stage can be controlled by the ratio of the feedback resistor to the input resistor or impedance. (For low closed-loop gains anyway. The open-loop gain of a single inverter is not very high. Three inverters DC-coupled in series have a lot of open-loop gain, but can get unstable.) Although a 4069 draws only about 1 mA from 5V in this configuration, silicon-gate devices (74HC04, etc), will draw quite a bit more. And different brands of chips can have widely differing characteristics. If the frequency is low, micropower op-amps are likely to be better.

Resistor construction has changed over the years. It is now almost
impossible to buy a carbon comp resistor (those were the real
non-inductive types), they are all special order. Virtually all carbons
now are inductive, the circuit requirements determine if the inductance is
a problem or acceptable. Wes described the construction perfectly.

Be sure to check out any resistor type carefully before using it terminate
or load a VHF or UHF system, and even if the application is critical in a
HF system. This includes metal film types!

Another point to consider is how well decoupled is your antenna feeder? I used to use a co-ax fed multi-band hf dipole, complete with the usual balun, this always resulted in some computer hash on the radio. As an experiment I tried an open wire fed doublet antenna with a short (18") length of co-ax to a 4:1 balun connected straight to the back of my TS-850SAT, wow what a difference, the interaction between the computer and the radio had improved by quite a few dB's.

I have had a similar problem with a DeeCom 4m aerial and my tnc, replacing the amateur DeeCom aerial with a commercial low band end fed aerial on the same feeder reduced a hash problem to the point where it wasn't significant.

This obviously doesn't "cure" the computer from throwing out spurious signals, but it might help avoid picking so much of it up!

I think Optoelectronics, the frequency counter people sell as module
the guts to one of their counters. Radio-Electronics magazine had a
bunch of counter projects 3-5 years ago where both Optoelectronics
and Startek had kits of various counters in their lines.

Red Lion Controls (sold by Digikey) has some counter modules, but I think
they're more process control indicators like tally counters and tachometers.

1420 MHz is an emission line of neutral hydrogen. It is used by radio astronomers to map hydrogen density in the Milky Way galaxy and beyond. A small frequency band surrounding 1420 MHz is a protected radio astronomy frequency and no other manmade emissions are permitted there.

This is absolutely correct, and in my previous post on this thread I
probably din't make it clear. Only in very low resistance values is the
film truly cylindrical. Usually, it is deposited that way and then
trimmed by burning a groove in it to increase the value. This
groove may be short, leaving the element mostly intact in some cases
but it all depends on the resistance per square of the film.

True again, which is why I too suggested paralleling a number of lower wattage
parts. At least this way, if the parts are slightly inductive, they wind
up in parallel.

Brian Webb (102670.1206@CompuServe.COM) penned:
: I'm trying to find either an IC or a schematic for converting
: serial-parallel.

: I own a solid state radioteletype decoder (circa 1980) designed
: to work with serial printers. However, my printer, like virtually
: all others is parallel.

: Regards,
: Brian Webb, KD6NRP

Most printers around that time were serial. There are still many old
printers that are serial. And believe it or not, most of the printers
made today are serial.

Well that's a bit of a fib. Most of the printers, like LaserJets and
DeskJets, have both serial and parallel ports. And you could use either
one on the newer models. They switch automatically between the two ports.

The computer stores like Fry's and MicroCenter sell a serial to parallel
box for around $40 US. You can often pick up a cheap buffer box that
will do the same for a few dollars at a swap meet.

You should check to make sure that the box you get can be set to the correct
baud rate. Some of the older stuff may run at very low baud rates, and
most stuff today runs at 1200 bps or faster.

> datwyler@aros.net

To modernize something a friend and I did many years ago, you might consider the following: Use a small audio amplifier (the "modulator") to light a LED. (We used a neon bulb) You will need some dc bias (the "transmitter") to provide a carrier. For amplitude detection we were able to borrow a 16mm movie projector. The audio portion of that has a phototube and audio amplifier. So, all you have to do is dim the lights ("QRM") and shine the LED in the direction of the phototube. It's somewhat less "quick-and-dirty" if you have to make your own light detector, but a phototransistor and an audio amplifier might not be too complicated.

This demonstrates AM with the added bonus that the signal is visible.

Good luck,

O.K. Ian,
The source is often the bias generator.
With the gate at zero volts, the current thru the resistor
set up a voltage drop to cut off the FET. You shuld have
the complete specs for the device so you can make a good
guess at the value required to bias the device correctly.

John,

About the most I have seen a crystal "pulled" was in the range of a
few hundred ppm (<1000ppm). Let us know how your "tuning" goes.

Hope this helps,

Mike Wyatt

5872. Any schemes or info for building a 'cellular phone range' transmitter?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-09 00:00:00 UTC
From: koenknip@innet.be
Message-ID: <koenknip.13.00129D96@innet.be>
Source record: 109066

I was wondering if it was possible to build a radiotransmitter which only produces a noise signal to disturb cellular phone usage indoors.

If so, can anyone send me an easy to build project including a scheme and a components list ?

It should be a low power transmitter, with a disturbance range of about 30 by 30 foot, with no other equipment (radio, television, etc) being harmed of course.

Any info (also on frequencies for cellulars in Belgium (GSM)) to :

koenknip@innet.be

thanks in advance

5873. Re: What's at 1420 MHz????

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-09 00:00:00 UTC
From: demerson@bass.tuc.NRAO.EDU
Message-ID: <4acc81$fjj@solitaire.cv.nrao.edu>
Source record: 109067

Probably the single most important frequency in radio astronomy is
that detected from atomic hydrogen in the interstellar medium, at
1420.405 MHz. Because of Doppler shift from the motions of interstellar
hydrogen the emission can be detected over a range of frequencies.
The band 1400 MHz to 1427 MHz is a protected radio astronomy band.
If you have a sufficiently sensitive receiver and antenna, it's
possible for an amateur to receive emission from the hydrogen line in
our Galaxy. It would appear as a slightly higher background noise,
spread over a few 100 kHz near the rest frequency of 1420.4 MHz.

Hope this helps,
regards,
Darrel Emerson, AA7FV.

From: at007@FreeNet.Carleton.CA
Message-ID: <DJBzMx.J09@freenet.carleton.ca>
Source record: 109069

I am wanting to build an antenna for use with a Standard C228A
2 meter and 220 ht. I want to put this in a tree 80 feet high.
What I was thinking was to make 2 whips 1/4 wave and attach each
whip to a single so239 connector. Any ideas of maybe a simple
design that might have a little gain also? Needs to be fairly small
and simple.

Thanks for your ideas,
Dan Barnawell (N4YSV)

Good suggestion. I"ve used those radios for all sorts of things and as
you say, there's a lot of stuff for $7.00. They use a single chip AM
receiver, a few discrete components, a ferrite loopstick and very little
else. Overall gain isn't very high however and a transimpedance preamp
will be required to match the detector to the RF input and provide some
low noise gain.

years ago 3.5 to 4.0 mhz xtals were pulled down 2 khz or so with a pencil, but
those were mounted in pressure holders that could be easily dissassembled
for the dirty work. If you went too far and xtal died, erasing the lead would
usually restore operation. With newer plated xtal holders, much less movement
is possible. Neighbor vacuum deposits some aluminum (i think) and really does
get some loading done. lacking proper equipment may make this impractical
for small operations

:
: Hello all, I am having a great dilemma in finding a good (and RELATIVELY
: cheap) circuit simulation program for my RF (VHF to MICROWAVES) circuits.
: I have been using CALTECH'S PUFF which works OK but has a few too many
: liberties when analysing Microstrip circuits, particularly coupled
: filters.

If you're interested in modelling coupled-line filters, you need a physical modelling program.

If that isn't your primary need, you might try SCALC as a general-purpose VHF-microwave network simulator and optimizer. Please excuse the "canned" description below.

****

S-CALC is a powerful microwave S-parameter analysis and optimization program that doesn't cost thousands of dollars. Developed by Roger Blackwell, G4PMK and Ian White, G3SEK, the SCALC program can analyse the performance of almost any RF network based on standard components and building blocks. Unusually for a low-cost RF design program, SCALC has an optimizer: starting from your initial design, it can automatically improve the performance of the network towards your chosen goals.

As well as having a built-in circuit editor and its own large library of active device data, SCALC can import your own device data in industry-standard file formats (S2P and PUFF). Output from SCALC's performance analyser can be in several formats including colour graphs, Smith charts and tables of gain, impedance etc.

SCALC is easy to understand and use. When G4PMK and G3SEK developed SCALC from the original program ALMOND by Chris Trask N7ZWY, they paid close attention to the user interface and have also produced a comprehensive manual with lots of explanation and tutorial examples. If you already know a little about S-parameters, you can start to use SCALC very quickly because the Shareware release includes the full tutorials and example files. If you're still learning about RF design, SCALC and its tutorials will help you on the way.

SCALC is Shareware with a specially low registration fee for radio amateurs. The registered version also includes a printed manual, libraries of device data and datafile conversion utilities, and technical support.

Requires VGA, 640k, DOS 3.2 or higher.

SCALC.ZIP (152505 bytes) is available by ftp from:

scitsc.wlv.ac.uk /pub/hamradio/programs/g3sek+g4pmk

demon.co.uk /pub/ham/circuit-design

oak.oakland.edu /pub/hamradio/pc/ham-utils

and also from the CompuServe HamNet library.

Laser light is easy to detect, the problem is it takes about 500ms for the laser gun to take 10 readings and average your speed. When the patrol officer is looking at your car through the sites the laser is not on, when he pulls the trigger the laser turns on and he can see the beam through the cross hairs, 1/2 sec. later, your nailed. By the time your laser sensor goes off its too late. A lot of the radar detectors sold now have laser detect. But if the patrolman really knows how to use the laser system he's gonna get you.

Drive safely,

Tim, ka8ddz

5884. Looking for specs of MV2113

Newsgroup: rec.radio.amateur.homebrew

I'm trying to find the specs for the Motorola varicap MV2113 or 2114, most importantly the capacitance. The closest I could find was in the ECG manual that said the 614 will sub for the MV2111 and it has 33 pF at 4VDC. I assume that the 2113 has a higher capacitance than the 2111. All the xref's that I've seen don't go any higher than the MV2111.

I tried the Moto Web page thru Engdahl's and I couldn't find anything there, just search temorarily unavailable.

If I can find out the capacitance, I might be able to put two of the ECG or other subs in parallel to get the required capacitance.

These are in a two lead TO-92 case. There used to be varicaps that were in regular glass diode cases, and I suppose they could be used, too, if I can find a substitute.

I cna sure see the flicker when testing some photo sensor we work with. I
have to either use a lowass filter or DC on the bulb to keep from having
alisases form hell. The sensors will only be used in sunlight so normaly
we don't filter them at all.

The level of the flicker is pretty low carried on a substantial offset. I
get a more marked 120 hz effect from floresent lights. You should be able
to frequency modulate them at autio rates. Or you might be able to do AM
with magnetic coils that choke off the energy to the bulf. It would still
have to carry an offset to keep the bulb conducting.

Good luck

All that is required is to bias the LED on (this provides the "carrier") and make sure the audio is low enough level to avoid driving the LED off, (i.e. avoid overmodulation) and you have a pretty good demo of AM.

Jim

Siliconix is a manufacturer of FET's. Along with their reasonably
excellent data, they do have some very nice application notes in their
data books. Most technical libraries (like at the university) have
data books.

5893. WNTD: Circuit for 1750hz ToneBurst

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-10 00:00:00 UTC
From: Poltergeist <rst@roogna.demon.co.uk>
Message-ID: <818622807snz@roogna.demon.co.uk>
Source record: 109006

Hi There.

Can anyone supply me with a diagram for a small reliable 1750hz tone burst??
I want to fit it between a Speaker/Mike and a PMR, hence it must be small,
battery operated (abt 1.5volts) and push button operated.

Thanks for reading this and in advance for all replies.

Roy G7KGT

Wonder if you've tried this. Since an incandescent bulb doesn't noticeably
at 60 Hz, I'd be surprised if it would follow audio at all. The scheme
should work with an LED, although the distortion might be pretty bad due
to the nonlinear nature of the LED and detector.

PADS-PCB has a shareware version that works well for small boards. It's limited in the number of parts you can have, 70 I think. The first version was called Padsdemo. There is a more recent version called Testdrive. I think Testdrive has a better autorouter, but I've not taken the time to convert to it. I don't know if you can still get it from the Pads guys, but I've tripped over Padsdemo on the www. It comes with a nice part library....and if your invention works, you can have the board made commercially.

Hello.

Could someone point me in the right direction? I'm looking to built a (hopefully simple) FM receiver that is channel specific. I'd like a little breadboard project that picks up .. say .. the 90-100 MHz FM range.

I've done alot with shortwave/AM radios, but never've really fooled with FM.

Good places to find schematics for FM projects?

thanks in advance,
-tony.

5901. Re: What's at 1420 MHz????

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-11 00:00:00 UTC

Message-ID: <4aho0q$5dd@longwood.cs.ucf.edu>
Source record: 108924

If I remember my astronomy classes, 1420 MHz is the spin flip
frequency of the hydrogen atom. Radio astronmers use it to
map the distribution of hydrogen in space. Digging deeper the
OH radical has a radio line at 1680 MHz(?) so that the region
between 1420 and 1680 has come to be called the water hole
(H to OH) by those who SETI (Search for Extraterrestrial
Intelligence). Presumably any life forms will know water
and think this frequency range as nice a pun as we do.
Sort of an intergalacitic calling channel. Also
I think the galactic radio noise has a minimum in this
general frequency range.

I just reread Motorola's application note on temperature effects
on varicaps, but didn't find it very enlightening. It had a
bunch of random data of tempco of various varactors at various temperatures,
but no unified theory of compensation except for mentioning in passing
the 2mv/deg C compensation by using an auxiliary diode with DC bias on
it to give a variable offset that you alluded to.

If anyone has any other info in this area, I would greatly appreciate
hearing about it. If not, I am going to have to conduct my own study
here at HP pretty soon for a project I am working on.

: . . .
: What I'm seeking is basically a short-range DC transmitter/receiver pair
: that functions much like a garage door or gate opener (and in fact it is
: the latter for which the pair will be used) that offers a fairly-high level
: of security. Note that 12VDC is all that's available to the receiver, as
: the gear-motor driven gate is in a remote location (powered by lead-acid
: batteries charged by solar panels).

: The best thing I've found so far is certainly cost-effective but has only
: 2^8 combinations and thus isn't very secure. . . .

Regarding increasing the security. A fairly simple scheme would be to
use 2 of the low security (2^8) units configured so that after the first
received the correct code it opened up a short window of time in which the
second unit would be able to accept its code and activate your device.
Obviously more elegant solutions are possible, but this might get the job
done with the greatest use of standard parts.

Peter,

You may want to look into APLAC. A free demo version is available through the University of Helsinki in Finland. If yoy have WWW capability, you can find their web page at http://picea.hut.fi/aplac/main.html.

The demo is almost unlimited in capability limited by a file size of 256 Kbytes. It is a circuit and systems symulator covering dc through microwaves. It supports several types of optimizations, handles stripline, can simulate complete communications systems from analog based through digital modulation.

It is available in several versions including HP workstations, MS Windows, Sun, Solaris, Linux and DEC Alpha. The best thing is that it is free for the downloading. One minor drawback is that it is not a schematic input simulator - it requires an input file. The output analysis available are operator selectable and includes the usual amplitude and phase responsesand Smith charts.

The document files are also downloadable. They are all zipped and expand into around 11 meg of postscript files. They require a postscript printer or a utility such as ghostscript to print on a non postscript printer. The manuals print out around 1000 pages of text.

The full commercial version goes for over $4000.

> Why 1420 MHz?

It is the 21 cm spectral line from interstellar hydrogen. It is produced
from spin reversals of the only electron in a hydrogen atom.

What was the noise figure quoted and from which direction was that
measurement obtained ? There are large variations in the 21 cm emission,
while most radiation comes from the Milky Way.

Another well known spectral line is the hydroxyl (OH-) spectral
line at 18 cm (1667 MHz).

> Organization: -.-. --.- -.. -..-

The ultimate CQ DX was attempted by the SETI (Search for ExtraTerrestrial
Intelligence) people who transmitted simple "pictures" at 21 cm towards
some nearby stars, hoping for a reply from some intelligent creatures
that were hoped to live near these stars :-).

IMHO, the high noise 21 cm spectral line is the worst place for such
experiments.

> Also has anyone heard of a NASA beacon that was left at the
> moon around 2.4 GHz?

Is this the transmitter that was in in the ALSEP scientific station
that was left on the moon by the Apollo astronauts ? The SNAP nuclear
batteries that powered these stations have depleted long ago, so I doubt
that there are any more operationals beacons.

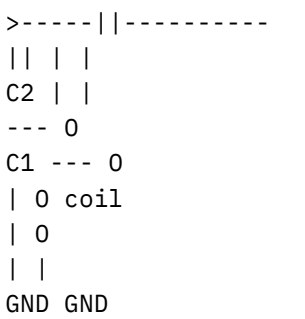
Hi!

First I want to clear up what NMR has to do with amateur radio: we also deal with HF in the MHz range, need things like resonant circuits, impedance matching and so on.
So the question I have may be somewhat stupid, but is ABSOLUTELY urgent for me. I want to get a resonance circuit at approx. 90MHz, consisting of a small coil as 'antenna' (<1cm long, <5mm diameter), one parallel capacitor (some pF) and one series capacitor (also some pF). It should be a parallel resonance circuit of the following setup:



The input is via a have-wavelenght-line, fine tuning will be done with a matching network after that. Now the trouble is the tuning/ matching of the circuit shown above. Can anybody tell me a convenient way to do it? Tuning equipment will be a Magic-Tee and a vector impedance meter. Setting up a SERIES resonator is no problem, but the parallel troubles (BOTH Cs influence the resonance condition!). Hints on literature (not the radio amateurs handbook, I also tried to find something in it) would also be helpful...

Thanks in advance,

Thorsten Feiweier

The easiest tuning setup to use is an rf bridge with a diode detector, a swept-frequency rf generator, and an oscilloscope (low freq only - need not display the actual rf signal, just the diode-rectified result) for the display. With this setup, you will see a voltage which is related to the reflection coefficient of the probe plus cable. The voltage goes to zero when the circuit is matched. Adjust the parallel capacitor to put the "dip" at the desired (Larmor) frequency. This usually requires a couple of iterations.

The setup described above is built in to many commercial NMR systems (e.g. Nicolet, GE-NMR, Tecmag, possibly some Bruker systems, and others). The bridge circuit may be taken from the amateur radio handbooks. I like a Wavetek 2061 signal generator, but there are lots of other suitable ones (an old TV-repair sweep generator, once used for IF-strip alignment, can be modified for the desired frequency if cost is a concern).

I do not recommend remote tuning via the half-wave cable, unless it is absolutely necessary (e.g. the probe is in a He cryostat). This is because:
1) the tuning and matching range will be severely limited.
2) there are significant losses in the half-wave cable (reducing snr).

Good luck!

Roy G7KGT asks:

> Can anyone supply me with a diagram for a small reliable 1750Hz
> tone burst??

This is a fairly tough assignment, since you need 1750 Hz +/- 1% over a wide temperature range. Check out the material in the RSGB VHF/UHF manual, and the Radio Communication Handbook.

What I did when I needed a toneburst for a trip to England was make a TTL crystal oscillator with a 7400 and a 3.58 MHz NTSC colour-burst crystal, divide it by 2048 with a handful of 7493s, and apply the result (slightly below 1748 Hz) to a little speaker. Worked perfectly the first try, and being based entirely on junkbox components, cost me exactly nothing. A more concise version might use one of those nifty CMOS ripple counters for the division by 2**11.

Such a concoction - even with CMOS - is unlikely to run on 1.5V, unfortunately...

When I was in junior high school (quite some time ago, now), I connected
an audio transformer's secondary winding in series with a flashlight bulb and
batteries. The primary was connected to an audio amplifier (tube). Using a
phototube as a detector (connected to the input of another amplifier), I was
able to transmit audio up to about a hundred feet. It was certainly not high
fidelity, as the frequency response drops off very rapidly. Nonetheless, one
can certainly transmit intelligible voice with an incandescent bulb (at least
with something like a flashlight bulb).

]for $1.60. What does that have to do with the problem, $500 multipurpose
]programmers not withstanding! really I do not give a hoot that Motorola
]sold one billion microcontrollers. I want one that works for all of us!!

I get your point. I was trying to point out how often a uC can make short work of many of the common task the average hobbist is trying to solve, not just professional EEs. If you just want to play around and have some fun get a PIC 16c84 for $10 US. Its EEPROM so you can erase and reuse it and the schematics for a home brew PC serial port based programmer are on the net. Total cost $20 and a weekend of your time. Digital and uCs and uPs in particular seem to be seen as overwhelming by the average ham. Kind of like RF is magic to the average guy. Actually digiatal is easier. I can write a reasonable complicated program for my favorite uC in a few beers and have it compile right off the bat. Now designing a 418 MHz 50 ohm 3.5 inch strip line folded dipole antenna is a lot of work.

If you are referring to microwave ovens, they used to operate
around 900 MHz, and then were moved to 2.45 GHz. The frequency
of a microwave oven has *nothing* to do with any water resonance
frequency. It has a lot more to do with the politics of spectrum
allocation, and secondarily, the physics needed to make a safe and
useful cooking tool.

Fortunately for those searching for extra-terrestial intelligence
(SETI), microwave ovens don't operate near the water hole (1420
to 1660 MHz).

Tom:

So true. It is getting increasingly difficult to find true, carbon composition resistors anymore. Fortunately, Allen-Bradley still manufactures them in 1/8 watt up to 2 watt ratings. Two models are available: RC and RCR, and both are available in MIL-Spec versions.

As you indicated, even the best resistor can behave as an inductor at high frequencies.

BTW, there is a form of wirewound resistor that's used extensively in broadcast transmitters. The return winding is crossed as it comes back onto the resistor. The idea here is to form a wirewound resistor with inductance cancellation. It's still not perfect, but works quite well in high power applications.

Message-ID: <30CCB040.13FD@jpaw.com>
Source record: 108945

Years ago I helped a fellow graduate student who need 22 MHz inside his dewar for a double resonance experiment. We used a quarter wave line, matched to a 50 ohm source at the shorted end and tweaked the tuning with a variable capacitor in a box just above the dewar where the line size shrank to go into the dewar. The line outside the dewar was 2" or 3" ID because we were trying to get a high voltage at the experiment and required several hundred watts to overcome the losses in the resonator.

Basically, if the line is relatively short, all the higher order modes will be relatively far away in frequency. If you use a quarter wave line, your operating resonance will be the lowest one.

All of this is straightforward. What exactly is the problem? Do you want to match to a 50 ohm source/load? Why are the capacitors there? If the are the first approximation to an impedance match there is no reason not to use them, but if the object is to extract as much energy as possible from the circuit, the don't do much for you except possibly add dielectric loss.

Interesting !
My buddy is a designer at the firm that designes and manufactures the Radar-detector-detector. They are simply very sensistive receivers tuned to the IF of a radar detector. A lot of stray energy gets emitted from the small receiver feedhorn built in to most radar detectors. It would be pretty difficult to shield the L.O. enough so that stray RF does not escape. I'd be interested in hearing how this "ghost technology" works unless of course they are referring to the laser units.

Message-ID: <4aic53$n2j@mcd1.fm.intel.com>
Source record: 108948

All,

What is the best way to add AGC capability to the SWAN 250 radio? This radio has no AGC, so when I am listening to a weak signal during a contest my ears will get blown out by a local contester!

This is a tube type radio. I figure a feedback from the audio output to the audio amplifier input could do it. Is there any other ideas or designs on how to do an AGC on a tube radio like the Swan 250?

I've got the radio for free, so don't tell me to buy a new radio. I simply can't afford it!

Thanks,

Also, I read that fellows have best results when the absolute bare
minimum of drill shank is exposed from the chuck (just enought to get
through the board) and the table is brought as far up as possible to
minimize quill extension (and resultant wobble). What happens with
this stuff -- do the printed traces lay down on the board or do you do
a negative image and the fields take the toner?

5932. Re: JFET Source Resistor

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-11 00:00:00 UTC
From: "Paul Christensen, N9AZ" <paulc@jax.se.continental.com>
Message-ID: <4ahfb8$s4a@usenet.continental.com>
Source record: 109019

The method I use comes from my trusted first-year, EE college textbook:

Find the transconductance value of the FET from the data sheet. If it's given a range, take the geometric mean of the two values. The source resistor value is the reciprocal of the Gmo (transconductance value).

Example:

My MPF-102 data sheet shows a Gmo value of 5,500 uS. The reciprocal is 181.8 ohms. 180 ohm resistors are generally easy to find and will work quite well.

Of course, a measured Gmo value will give a more accurate result.

I don't have my ARRL book here, but coax makes a great capacitor. Look in the tables and find out the capacitance per foot and
measure and cut the appropriate length.

I have also made "trombone" capicitors with brass tubing inside and outside plastic tubing.

THe advantage of the coax capicitor is that the power handling capabilities are known.

Hope this helps, Mike "777" KF4FDJ

Several have asked why NF was measured at 1420 MHz in the recent Feedpoint. I presume that this refers to North Texas Microwave Society journal.

The Microwave update for 1995 was sponsored by NTMS. As a part of Microwave update, the SETI League (search for extraterrestrial intelligence (is there any terrestrial intelligence?)) gave a presentation on Hams using amateur microwave equipment to search for interesting signals. That would explain why that frequency was tested and reported. I didn't get a chance yet to digest that issue of the Feedpoint, but I presume these are the result of the NF measurements done Friday night at the conference.

It depends on what you mean by "secure".

If what you need is a system which has a huge number of possible codes, there are several on the market. One of these the "DX" wireless units made by Linear. Each transmitter is individually coded at the factory, and the receiver must "learn" each code it is supposed to accept. The basic receiver can learn up to 16 different transmitter codes. There are larger systems available. Any alarm company can get them for you, as can the installers of electric gates. Look for a company which advertises that they do "access control", and they'll know what you're looking for. By the way, one advantage to these systems is that a lost transmitter can be programmed out of the system without affecting the other valid transmitters. And yes, they run on 12VDC.

If what you need is protection against a "code-grabber", which can receive, store, and retransmit whatever code your transmitter sends out, you'll need a rather fancy system which transmits a different code each time you push the button. This is used in the high-end car alarms, since it's worth going to this much trouble if you want to steal a Ferrari. But it's probably overkill for a gate application. As far as I know, this type of system does not handle multiple transmitters.

5940. ARRL books

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-12 00:00:00 UTC
From: Lanier.r.a@nort.bwi.wec.com
Message-ID: <DJHptF.1L2@news.zippo.com>
Source record: 108877

Has anyone purchased the following books:

Introduction to Radio Frequency Design by Wes Hayward

QRP Classics

Both are available from ARRL. I looking for a good intermediate to advanced book on RF design, one that has practical circuits, but also detailed theory.

Any comments are welcome.

I make sure that there is a "hole" in the center of the pad in the
artwork, so that there is a copper "donut" on the glass-epoxy. The
resulting low spot of no copper in the middle of a copper circle
acts like a center punch, and works as a drill guide.

>Also, I read that fellows have best results when the absolute bare
>minimum of drill shank is exposed from the chuck (just enought to get
>through the board) and the table is brought as far up as possible to
>minimize quill extension (and resultant wobble).

This works well also, and the drills will last much longer if you
spend the extra $ and get the carbide bits rather than the steel.
Kinda like alkaline vs carbon-zinc batteries: 5x the life for 3x the
money.

One trick that I do when I lay out a board: put your callsign,
the date and the magazine name and issue that the project was built from
on the layout: something like "WA6ILQ 9-94 from QST 6-94". Helps
when you are trying to fix it 9 years later.

I also stole an idea from DEC computer cards: add the following
string to an edge of the card "ABCDEFGH". The first time you make
a mod to the board place a solder blob on the "A". Then add a sheet
of paper to the documentation describing modification "A". If you make
another mod, blob the "B", and add a sheet to the file. Etc.
If you have several different versions of a project around, it makes
it simple to figure out the revision level.

de WA6ILQ

I tried that but the PnP blue film doesn't do those too well. Someone suggested using a pin on the film before the transfer. I'll try that next time.

>>Also, I read that fellows have best results when the absolute bare

Tried that on my second board, and it helped somewhat.

>This works well also, and the drills will last much longer if you
>spend the extra $ and get the carbide bits rather than the steel.

I'll be looking for some before my next project.

>One trick that I do when I lay out a board: put your callsign,

Yep, I did that, I hate it when you go to fix something you built years ago, and don't have a clue how or why you did it.

>I also stole an idea from DEC computer cards: add the following
>string to an edge of the card "ABCDEFGH". The first time you make

><BGB> http://ccwf.cc.utexas.edu/~lihan/

For garage door openers it is pretty easy to monitor a broad band of
frequencies and grab your code out of the air. A protection for this
is to use the interior button to open and the hand transmitter with a
DIFFERENT code to close. Then have a third code on the hand
transmitter to re-open if the first code is tried again within 30
seconds of moving. For the unskilled homeowner, though, it is better to
make a door opener which has a microcontroller which detects multiple
attempts nearby to open your door, and it automatically changes the
open code to a longer code you would need to switch to with your hand
transmitter!! This also gives you warning that someone may have
attempted entry! The best is a computer that locks the system and
calls security if anyone sends a binary sequence of numbers in obvious
attempt to open yours or nearby garages! Sort of like the ATM machines
which keep your card if you fail to enter the right PIN number three times
in a row in any day or week! Don'tcha jus'luv redundancy? "PIN number"!

5948. Printing directly to PCB with an ink jet printer ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-12 00:00:00 UTC
From: jay@rmii.com
Message-ID: <jay.39.001F83F7@rmii.com>
Source record: 108885
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.cad,sci.electronics

Hi;
I recall seeing bits and pieces of a thread about doing PCB's with an ink jet printer. I have been doing artwork with a number of laser printers, and have yet to find one with decent registration. Registration is crictical to me as I am trying to drill out the holes with a NC drilling machine. Plan B use an ink jet printer instead. Also I intend to print directly to the PCB and skip a bunch of steps. So what I would like to know is the following.

1. Has anyone done this ?
2. If so, what printer did thay use ?
3. What ink jet printers have a flat paper path ? Color would appease my wife and kid.
4. Is registration any better than what you would get with a laser printer ?
5. Any other ideas ?

Thanks !!!

Sorry I missed the fornt end of this thread, so I don't know exaclty what you need but the 74xx299 is a 20 pin parallel in and out universal 8 bit shift reg. It should do the trick. Tons of other options as usual. Since your going to have to write a driver, you might want to use a microcontroller with a serial port to make you box look like some other modern device that is supported by whatever software is going to be talking to it.

5950. Ham stores/Chicago, 500W dummy load

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-12 00:00:00 UTC
From: gwilliam@xnet.com
Message-ID: <4akgih$j98@flood.xnet.com>
Source record: 108951
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I am a non-ham who needs to buy a 500 W dummy load (for 13.56 MHz, preferably with a BNC connector) for an experiment in an industrial setting. Needless to say, I need this soon (like tomorrow). Can anyone tell me a ham store in the Chicago area (North/West would be preferable but not required) or a mail-order outfit that would be able to supply this item quickly? Alternatively, does anyone in the Chicago area have one that they could lend (rent) to us for a few days? Although it might be possible to build a dummy load relatively simply, I would prefer not to do that for reasons of repeatability (we may need to repeat this experiment in another location with different equipment at a later date.)

Any help would be appreciated.

Some years ago there was an article in the now-defunct "Ham Radio" on PCB etchants. I recall the best solution was Cupric chloride and some other additives. The really cute thing was that it was possible to regenerate the solution by overnight aeration. (I think that it was possible to end up with more etchant than you started with.)

Anybody have this article ? More importantly, has anybody tried it with success?

And it varies with frequency, too. For a given product, Er is
usually controlled better than board thickness.

I've always read that steel can't be used for transformer cores at RF because its loss is prohibitive at higher frequencies. However, when a cable is wound around a ferrite rod or through a toroid for purposes of RFI prevention, it shouldn't matter whether the core is reactive or resistive. Is it a waste of money to use ferrites for this, or does plain steel "disappear" at RF due to hysteresis?

Yes, that works well for noise relatively far from the carrier. I've done it a number of times. However, if you're going to go to the trouble of getting a crystal for each measurement frequency, you might as well use the crystal to make a VCXO, which is actually easier than making a filter. You can then lock the VCXO to the source under test and look at the baseband noise with an audio spectrum analyzer (home brew 3048 architecture).

It looks to me that C2 is used to isolate the coil from DC. C1 and
the coil should set the resonant frequency. The ARRL Radio Amateur's
Handbook says that L=(a^2)(n^2)/(9*a+10*b)

where L is in uH
a= coil radius in inches
b=coil length in inches
n=number of turns.

Use the size of wire that will just complete the number of turns
required in the space required in order to have the stiffest coil.

Use a large C2 to take out as much of its influence as possible.

At 90MHz, you can tune the resonant tank circuit in various ways.

One is to get a "gate dip oscillator" that couples to the coil
and displays when the tank circuit is resonant.

Another is to feed the circuit from an oscillator through a resistor
and adjust to get least current flow through the resistor, since
the tank circuit is maximum impedance at resonance. You do have to
be careful not to load the circuit with probes.

Hope this helps,

Jim Goecks WA7UKS

Snip
Snip
The 95 handbook published a neat adjustable tempco compensation circuit that should be adaptable to nearly any application with oscillators.

It consists of a bridge circuit that has a thermistor in each leg, one up and one down, a trimpot whose wiper is connected to the source voltage for initial balancing, and a 100K multi-turn pot across the bridge whose wiper is connected to a varicap diode used to offset the drift of another LC or crystal oscillator. It is in the AC sources/oscillators section. Sorry I can't give page and actual verse, but I am using it quite happily. Very adjustable.

E-mail me what file format you can use and I will send you the schematic of its application in my "stuff."

Steve Schiller wrote:
> If you want to make a cheap one suitable for UHF frequencies,
Take a piece of copper, aluminum or brass tubing at least
one-half wavelength long at your frequency, sized for a slip fit
over the center conductor of RG8/u type coax. Drill holes every
cm or half inch or whatever. Make a small E-field probe that
has a stop so it sticks in the same distance every time and
measure E (V) as a function of position. The same thing works
with waveguide. Just space the holes appropriately so that you
get 10 or so points per half-wavelength, and away you go. A
cheap and easy prbe can be made from a short length of
semi-rigid line coax, the kind available surplus with SMA
connectors on the end. Cut off one connector. Cut away the
outer conductor to expose a length of center conductor. Solder
a brass washer to the outer conductor about one wall thickness
(of your perforated line) back from the end. Drill the holes to
clear the OD of the probe outer conductor (About 0.094" for the
stuff I have) and probe away.

Save big bucks.

thorsten@news.hrz.uni-dortmund.de wrote:
Given L you want to get two equations in two unknowns to solve for C1 and C2. These equations are the impedance match condition and the resonance condition.

Consider a circuit like the one you drew with the addition of a resistance R1 in parallel with the coil, and call the coil L1. The resistance represents the losses of the coil and any coupling of the circuit to the outside world.

Now add a voltage generator with source impedance Rg from ground to C2 input terminal. The impedance Z of the generator + the coupling capacitance C2 is Z = Rg + 1 / (jwC2). (w is the angular frequency of excitation, omega) Convert the impedance Z to a shunt circuit with admittance Y= 1/Z. You get Y=(Rg-1/(jwC2))/(Rg^2 + 1/(w^2 C2^2)). The real (resistive part) of that is Rs=Rg(1+1/(w^2 C2^2 Rg^2). This is the resitance of the generator transformed by C2 to be in parallel with R1. Impedance match is achieved when Rs = R1. Thus, given Rg, L1 and R1, (or Rg, L1, Q1 = w L1/R1) you can calculate C2.

The reactive (susceptive to be pedantic) part of the shunt equivalent of Rg and C2 in series is just the imaginary part of Y. Namely, w C2/(1+w^2 Rg^2 C2^2). For a High Q circuit this will be indistinguishable from w C2. But let's not make any approximations at this point. Resonance occurs when the capacitive susceptance equals the inductive susceptance. That is w C2/(1 + w^2 Rg^2 C^2) +w C1 = w L1. Since you already know C2, w and L1, you can solve for C1. Note that, for high Q, the resonance condition is very close to w^2=1/(L1 (C1 + C2)).

Is this what you are trying to do?

Don't worry about an exact match, the losses with VSWR = 1.5, which implies that Rs = 1.5 Rg OR Rs = Rg/1.5, results in a loss of signal power of only 4%. The loss for 2:1 mismatch is 11%, which is probably not a big problem. The additional losses in the line due to the VSWR are very low compared to the normal attenuation.

Good luck,

Jim

Source record: 108973

I'm looking for suppliers of a DTMF decoder IC. Part numbers
SSI202P or 75T202 or CD22202E.

JDR Microdevices reportedly carries these, however the phone
number I have for them rings through to a fax. Does anyone have a voice
line to JDR?

I also tried Digikey...Their WWW page reported that they carried CD22202E,
however, after talking with them on the phone, they do not carry them in
stock.

I'm looking for a small quanity (4-6 parts) to start.

Any help would be appreciated, please post here or email me direct.

Thanks,

Peter / KD1XZ

>To me, this sounds like a job for a few Soundblaster cards.

Probably it is much simpler to do it in hardware...
Assuming you use FM, just high-pass filter the signal at a frequency
that is above the highest modulation components, e.g. 10 KHz.
There you will have only noise. Just rectifying and comparing those
values will give you the required selection criterion.
(this is the same method that the usual SQUELCH circuit uses. you may
be able to extract the required "rectified noise" signal from the receivers)

Of course the above can be done using DSP techniques as well.

This sounds like a great deal of overkill to me.

serial-to-parallel: isn't a UART what is desired? Maybe a couple
more chips to generate strobe pulses, and a crystal; but that should be about
it.

It would most definitely not do the trick, at least not without large
amounts of support logic. The original post was about asynchronous
serial transfer. It can be done with the HD6402 as mentioned, but it
will take a few extra chips to go along. A microcontroller with onboard
PROM would probably give the lowest chip count, but you need some tools
that not everyone has available (compiler/assembler, device programmer).

The 6402 is also suitable. This may be pin compatible with the AY-1013,
and is definitely still available. You can choose parity/stop bits etc
by hard wiring various pins high or low, and it will run up to 100Kbps.
This version needs a clock input, but there's also a 6403 which has a
clock generator built-in so you can just add a Xtal.

I've got both these books. The RF design book is excellent, and has
plenty of theory. QRP Classics has a lot of rather old designs (I
suppose that is why they are classics), with very little theory.

5984. Interfacing Ranger RCI 2950 to transverter

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-13 00:00:00 UTC
From: spbellamy@aol.com
Message-ID: <4anaqd$eiq@newsbf02.news.aol.com>
Source record: 108897

I wish to get on 6 meters and the higher bands and am considering using transverters like the type Down East Microwave sells. I am wondering if it is practical to buy a radio like the RCI 2950 Ranger, which is a relatively cheap way to get an all-mode 10 meter rig, and use it as the baseband or exciter radio for a series of different transverters.
There are a number of ways to interface a radio to a transverter. One way would be to take the antenna output and run it through an attenuator to supply the approx. 200 mw or less drive that the transverter is comfortable handling. The attenuator would probably be switched out on receive, but safeguard the transverter on transmit.
Another way would be to get low-level drive out of the IF section in the Ranger.
I am sure there are folks out there that have done this and I would like to have your thoughts on this project. Do you have a Ranger radio? Have you brought out the drive from the IF? How did you do it? What is the level of the drive signal? Is there a transverter group on AOL or thwe WWW?
Thanks and 73
AA8MX

I think you're right. Seems like the only solution that make economic sense.
Putting up anything other than a bare mixer for a reciever on 10.5 and 24Ghz is
going to cost a lot more than most customers would be willing to pay.
Well I guess a decent waveguide isolator would do it, but even the cost of
that would be prohibitive in the mass market.

In addition, the ARRL has "Solid State Design for the Radio Amateur", a
good combination of theory and practical circuits, and also the W1FB
notebooks ("W1FB's QRP Notebook" and "W1FB's Design Notebook") which
have less theory but lots of circuits. I took the coward's way out and
got them all...

Two places I like are Unicorn Electronics in CA (800-824-3432) and
Circuit Specialists in AZ (800-528-1417). They both carry the 2N4416,
as well as the 2N5486, a plastic device similar to the '4416 but at
about 1/3 the price.

There are two possible approaches:

Follow the information in the RF device data book by motorola,
however the transistors are not too cheap. (works for 40 and 6)

On HF there is the alternative of using simple power MOS-FET's.
QST had several articles about them.

5993. Radar Detector Detector

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-13 00:00:00 UTC
From: hopst@nrult1.dnr.ohio.GOV
Message-ID: <9512131350.AA12614@nralpha1.dnr.ohio.gov>
Source record: 108906

It's funny that Radio Shack is now advertising a "shadow" radar detector. A few years ago they had the most "detectable" radar detectors on the market. They used a Direct Conversion scheme where the local oscillator was right on the same frequency as the radar. My radar detector would always go off when a trucker passed me using one of those things. I could pick them up about a 1/4 mile away if they were coming towards me (and that was with a clunky Maxon detector).

There are radar detector detectors out there, as I have seen them. They look for any radiation in the 10 or 24 GHz band, generated by the local oscillators in the radar detectors. I haven't had a chance to check out the method on the "stealth" or "shadow" detectors, but I hear that they use extra shielding and pulse the LO and sample the incoming RF, rather than run the LO all the time.

--snip--

Tubes!! Yuuuck, (No disrespect to Mr. Weir intended) all that trouble for 100 watts? I'd try the Motorola EB63 from their handbook, you can get the board, and all parts less enclosure and connectors from Communications Concepts in Xenia Ohio 513-426-8600. The unit delivers 140 watts with 1-5 watts drive, broadband, NO TUNING, 13v @ 22amps. Uses MRF-454 transistors, a pair of them matches costs about $35 The whole enchilada is less than $100 I think.

Good Luck,

Tim Hynde

Richard Karlquist (rkarlqu@scd.hp.com) wrote:

: done it a number of times. However, if you're going to go to the
: trouble of getting a crystal for each measurement frequency, you might
: as well use the crystal to make a VCXO, which is actually easier than
: making a filter. You can then lock the VCXO to the source under test
: and look at the baseband noise with an audio spectrum analyzer (home
: brew 3048 architecture).

Yes! for testing a simple VFO or a complete synthesiser you need
only find a crystal within the tuning range and build a VCXO, or pick the
ends and centre of the range and build 3 VCXOs

It should not be too difficult to get a cleaner crystal oscillator
than VFO or synth for the sort of offset freq range that is of interest
for cw/ssb/etc modes that we use.

Say $10 to put a VCXO together, a few dollars more for a mixer and a
loop amplifier. 3585's still fetch a fearsome second hand price, so the
50kHz range of the original 3580A looks rather tempting. For a really
cheapskate home phase noise measurement, an old telecomms selective level
meter or "wavemeter" amounts to a hand-cranked LF spectrum analyser - I've
seen examples on sale at rallies for pocket money. The use of a step
attenuator and meter is a little tedious but may be somewhat more
accurate than a spectrum analyser. Arranging a sensible IF filter width
and integrating the filter shape to get its noise bandwidth need only be
done once.

Commercial phase noise testers are fine if you have access to them
but may not be adequate for true state of the art work.

8640 mixdown will show up the problems with today's synthesisers
well enough, and begins to be affordable by individuals.

VCXO mixdown will outperform the 8640 and threaten the commercial
tester, for an even lower price but is 1 freq per VCXO

Mixdown of an identical pair of the devices under test can be
similarly cheap AND state of the art.

The LF analyser is not a trivial matter for HF work. The HP3585 up
converts to a higher IF than you've just mixed down from, with a very
early frac-N synth. Tuned to VLF the phase noise sidebands of the synth
will leak into the IF, giving phase noise from the analyser modified by
the mixer drive level and the mixer balance....

Sometimes you just don't win

Still, I can't quite believe this sort of conversation is really happening on this group.... and what I wrote for the ARRL seemed to start it!

Cheers
David GM4ZNX

6009. Re: Resistor for RF power attenuator help needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-14 00:00:00 UTC
From: tomb@lsid.hp.com
Message-ID: <4aptt8$ec6@hpcvsnz.cv.hp.com>
Source record: 108831

In the ten or so responses I've seen here, I've seen folk mention that carbon composition resistors are getting hard to find, but nobody has mentioned metal oxide resistors. Commonly available in 1 and 2 watt sizes and perhaps larger, the ones I've checked in the 25 to 100 ohm range have very low parasitics. I use a pair of 100 ohm, 2 watt, units in parallel as a load for testing my handheld, and have measured SWR around 1.3:1 at 450MHz and for practical dummy load purposes, 1:1 at 2 meters.

Another very low parasitic power resistor is one made by Caddock: it's in a TO-220 style case. The biggest problem is the 4 or 5 pF from element to metal tab, used for heat transfer. You can dissipate 50 watts in one of these guys if you can heat sink it well enough. I think one of the other companies (Vishay?) has recently started advertising a medium-power resistor with low parasitics, too.

Hi there!

I am going to build a 1V2 rx with my 9 year old daughter. To make the whole thing a bit more historical, we are going to use the 6k7 and 6V6 valves. I got them already, some real nice oldies, but do not know the exact specs and socket terminations.

Who can give me this data?

JG>any suggestions.
JG>Jim, WA7NDD
JG>griffithj@ricks.edu

Dan's Small Parts and Kits lists them at $1.50 in the slightly outdated
catalog I have (1994-june95). You can't order by creditcard tho... But
the catalog has tons of cool bits and kits, all for QRP homebrewing ;-)
Address is: Dan's Small Parts and Kits
1935 So. 3rd West N0. 1
Missoula, MT 59801
Ph. 406-543-2872
I bought a kit from this guy a year or so ago. It took a little longer
to arrive than from some places since you have to send a check or MO,
but he sure has a cool list of stuff for sale.
Not a quick source for your 2N4416s perhaps, but I thought this source
worth mention.
Hope this helps someone

Has anyone tried one of those cheap($600) CNC machines to automatically drill boards? I'm thinking of buying one after the first of the year since the old eyes aren't much good for that kind of accuracy anymore.
The one I inquired about comes with a holder for a dremel tool, and a little CAD package to control it. A programmer friend of mine is interested in playing around with it too, and would probably develop some software to read drill files created by a lot of the pcb layout programs.

That's what I said, wasn't it. The 6402 is a UART, I just pointed out
another option that might save a few chips. Please note that most UARTs
would require a processor both for setup and for data transfer. The 6402
and a few others don't, all setups are done by tying pins high or low and
there are separate 8-bit parallel buses for transmit and receive.

>any suggestions.
>Jim, WA7NDD
>griffithj@ricks.edu

My Motorola data book has brief data for 2N5484, 2N5485, and 2N5486 FETs.
For detailed characteristic graphs, it refers to the 2N4416. From this
it appears that these are basically 2N4416 that have been graded into
narrower gate pinch off voltage ranges.

2N4416: Vgs -1 to -5.5v
2N5484: Vgs -0.3 to -3v
2N5485: Vgs -0.5 to -4v
2N5486: Vgs -2 to -6v

For more power gain, the 2N5486 is the hotter device.

The local small parts mail order house I deal with locally here in Phoenix
(DC Electronics 1-800-467-7736) has these parts (2N5484,5,6) for $.75 each.

Well, not to put the kibosh on your affinity for solid state thingies, but tubes (hot fets, radios that glow in the dark, etc.) are one hell of a lot easier to build and experiment with the first time around. You can mistune them, overdrive them, have them birdie and oscillate to beat the band and all you will get is a cherry red plate and/or popped fuse. Say "oops" and start over. With a transistor, say "oops" and buy another pair. The transistor will ALWAYS protect the fuse by blowing first.

Go back to the mid-60s to 70s ARRL manuals and you will find literally dozens of designs to choose from using TV sweep tubes, the old faithful 6146 (which, if done carefully, will do a credible job all the way to 144 MHz.) and a host of other methods.

Me, I personally like a pair of 807s plate modulated AM with an 811 ;-}...or even better, a pair of 1625s so I can run the filaments straight from the car battery with a dynamotor for plate voltage (lordy, am I showing my age or what).

The only caveat is that you AIN'T working with 12 volt tickles. 600 volts at half an amp will get your attention, so don't forget the shorting stick when you are working on these beasts.

6026. Re: How to add AGC to a Tube Radio?? (Swan 250)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-15 00:00:00 UTC
From: n4lq@iglou.iglou.com
Message-ID: <DJLsH3.8nn@iglou.com>
Source record: 108839

The 250 had agc. Maybe you're expecting too much. AGC controls the gain
of the IF stages based on the strength of the signal at the detector.
This is before it even reaches the audio section. You should normally
operate with the RF gain control turned all the way up (if it has one)
and adjust the audio gain for a comfortable level. When strong signals
are tuned in, the sensitivity of the radio should automatically decrease
and prevent the IF amplifiers from overloading. Volume may increase some
anyway since AGC does not regulate the actual audio amplifiers gain.

: This is a tube type radio. I figure a feedback from the audio
: output to the audio amplifier input could do it. Is there any
: other ideas or designs on how to do an AGC on a tube radio
: like the Swan 250?

: I've got the radio for free, so don't tell me to buy a new
: radio. I simply can't afford it!

Sometimes that is true, sometimes it isn't. I just checked some 2 watt MF
here that have 100 nanohys ind at a test frequency of 60 MHz. This
resistor would be worthless in most parasitic supressor systems.

This varies from manufacturer to manufacturer, my rule is to always check
'em and not assume they are non-inductive. .

Yes, someone mentioned them. I have some here, they work well. They are
kind of pricey for a tightwad like me. In thousands Allen Bradly *real*
carbon comps are 20 or 30 cents each.

>
>What is a substitute for the 2SC380Y ? Would a 2N2222 work ? They are
>both npn, but I don't know if the specs are close enough...

The 2SC380 is NPN, described as a FM/Amp/Mixer/Osc for use up to 250 Mhz.
Suggested replacements are: BF 240/241/254/255/594/595. A 2N2369A or 2N2222
should be OK, depending on the application.

What frequencies do they work on? Is it some audio-shift keying scheme
that could be recorded and played back?

Running through all combinations sounds more reliable, since it
does not require waiting around to record a door opening.

I've recommended these in the past, and have gotten one
complaint that they *look* too inductive to be useful.
I decided his eyeball's weren't calibrated accurately,
since he didn't even have a QRP rig/SWR meter to measure
them... Also, they are awfully rugged. 2 watt resistors
will actually take 2 watts for short periods of time. I've
run also run them at 72% of full rating for a couple hours
with no problems other than some melted insulation on the
clip leads. **Don't** try this with carbon compositions.

Check out the handheld swept reflection bridges from Advanced Electronics Applications (AEA, Inc, in Washington state, http://www.mvangel.com/aea/) in any recent ham magazine. These are much less expensive than a commercial swept RF generator, bridge, detector and scope ($200 ?). They can also be used right up to most magnets. The drawback is that they don't cover all the possible frequency ranges NMR folks like to use.

Drew,
73 Magazine had a couple of real neat transmitters a few years
ago, 1 - 40m and 1 - 80m. I built the 40m, about 3/4 watt, not many
contacts but fun to build. Don't have a scanner, but if you are
interesed I could mail you a photocopy of the schematic. They use
nand gates for oscillators and 2 or 3 2n2222's in the final. Real
simple, mine even worked the first time I turned it on!

Steve seems rather excitable!

Anyway, assuming that a potential unautorized user can "grab" the code from
your transmitter over the air, even a long code is not secure as long as it

is constant. The idea of using a different code for "close" is a very good one, as it is useless to a potential burglar and the one that you will transmit when leaving the garage. Unfortuantely, the logic of most garage door openers just has a circuit for "activate" which will either open or close depending on which state the door is in. But a low-security "close-only" receiver could be installed by using a limit switch or other means to disconnect it from the opener unless the door is open.

One low-tech approach that might suit many uses would be to allow the door to be opened by remote control only during certain times of day (when the owner is likely to be returning home). Burglars don't like to be around during these times of day. This does involve quite a trade-off in convenience.

Even simple receivers could be made immune to attempts to try every code by locking out for a period of time if several wrong codes are received. I don't know if manufacturers would boast of that feature or not. Some of the ones on the market are likely to contain it already.

A secure "open" code would have to vary over time, so that a copy of it is useless at a later time. Offhand, I can think of two ways to do this, but both would increase the cost quite a bit.

The first way would be a random challenge. This requires two-way communication though. The receiver generates a random number and sends it to the transmittter. Both units encrypt the random number with a secret number. The transmitter transmits the encrypted response, and if it matches, the receiver accepts it. Even if both sides of the communication are monitored, the secret number can't be determined. So the system is secure from a "code grabber" unless it happens to generate exactly the same random number for him so the same response would work. (and that could be prevented from happening by remembering which random numbers were transmitted recently and not reusing them).

Another way would be to install real-time clocks in both units. When activated, the transmitter encrypts its clock time with the secret number. The receiver accepts codes that are from times near the actual time. This has the problem of maintaining both clocks to the same time. A setup mode of some sort would be required where the transmitter sends its time reading and the receiver sets its clock to that time (this would have to be available only while the owner was present, by pressing a setup button inside the garage for example). Clock drift could be compensated for by the receiver making minor changes to resynchronize its clock with each successful decode.

If the resolution of the clock is on the order of minutes, it could be possible for a "code grabber" to re-use a code. Since the most likely application of the code grabber is to capture the code while the owner is leaving, a seperate "close" code is a very good idea. Another way would be to only accept a particular code once, i.e. require the clock in the transmitter to advance before it can be used again. On the other hand, if the resolution is too fast, cumulative error in the time could disable the

transmitter.

In either of these schemes (especially the random challenge), the secret number needs to be quite large to discourage exhaustive attempts to "crack" it (This wouldn't be as much of a problem with the real-time based scheme, the transmitter would have to be monitored at different times to try and deduce what the real-time setting is as well). Some means of configuring the transmitter and receiver to the same secret number other than the usual DIP switches is likely to be required. Probably the most customer-friendly way to do it is to manufacture each transmitter with a permanent, unique secret number, then transfer it over the air to the receiver during installation. Both the transmitter and the receiver would need "setup" modes, since the transmitter must not transmit the secret number except when no code grabbers are nearby. Unfortuantely, with this approach, if an unauthorized person can get phyical access to the transmitter for a short time, he could use it's setup mode to obtain a copy of the secret number and make a clone transmitter later.

Actually, if a burglar can get physical access to the even the most secure of transmitters, he could just open the door. This is how most garage-door opener facilitated breakins occur, despite the hype over the code grabber. The only defense from this would be to have a keyboard on the transmitter so the owner could enter part of the secret number before each use. This is likely to be too inconvenient for anyone to accept.

We have build numerous NMR probes before with the help of a RF sweeper and a
RF bridge w/diode detector. IMO a impedance meter is useless when you start
building the probe from scartch, impedance reading on the meter does not give
you a clue where you are going! With a sweeper, however, you see your resoance
peak and by looking at which way it moves you know where to adjust. The
y axis on the display indicates matching condition (with 50 Ohm match at the
baseline) and the x axis is the frequency. For example, if you resoance is at
the high freq side of your desired freq, you add more capacitance to C1. If
the resonance peak is far above the baseline you increase C2. You are right
abuot that increasing C@ will lower the resonance freq. On a sweeper setup,
you can build a probe in 10 minutes. Go buy/borrow a sweeper and forget about
the impedance meter. The latter is only good when you need to fine-tune the
probe which had been tuned and matched previously (like when you load the
probe with a lossy sample, etc).
In addition, we had replaced the RF bridge with a power combiner/splitter and
works just fine. You simpley feed one of the combine/split input with the
sweeper rf output and connect the sum port of the splitter/combiner to the
probe under tunning. A diode detector is connected to the other combine/split
input. If the load (probe) is tune and matched no voltage (or minimum) will be
detected at the didoe detector output. When your load is mismatched or
off-tuned, you will get a reflective out put at this port. We found this a
cheaper way than buying the RF bridge.
With such a setup, we build up to quadruple tune probe for our experiments.
They are being used by many NMR researchers in the US.

Finally if you checked out the recent TAMU Newsletter you will find an interesting ad. Some Canadian company is selling a hand-held device which will suit your need. It combines a synthesized RF source, RF bridge/detector and a LCD display (graphic). It is a handy little gadge for NMR work. The only drawback is that it is pretty pricy.

Hope this helps and let me know if you have further questions.

>N9RJW
>
Mike,
I work in an electronics shop where people need small boards (less than 8.5 x 11 inches) quickly and often, and we got tired of drilling them by hand, with the problems of connectors that wouldn't go in holes, missing holes in ground planes since they're hard to see, etc., so we built ourselves a machine to drill the holes for us. It's made of scrap dot matrix printers, with their precision ground rods, stepper motors, and belt drives. The accuracy is 1/300th of an inch, since the printers were 300dpi. With this machine, we can drill about 1.5 holes per second, and it doesn't miss any, either. My boss wrote the software to take in the pc board files (for small boards we use an old program called Smartworks, from Wintek) and it finds the holes, displays them on the screen, you line up two holes on the opposite corners, and it drills the board. He also wrote some software to interpret ASCII and Orcad drill files. We haven't drilled a board by hand since we built it, almost 3 years ago, and it is a lifesaver for me.
If anyone would like more details they can post to here and I'll see what I can do.

Also, we use a laser printer, sugar paper from DynaArt, a fuser roller from and old laser printer, and a bubble tank with ammonium persulfate with excellent results. Again, we have made hundreds of boards with good success with 16 and 50 mil runs, so if anyone has any questions we can help with, ask.

6042. WT: Info on Kokasi 800/900 mhz radio

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-15 00:00:00 UTC
From: drp@netcom.com
Message-ID: <drpDJn2Lw.48t@netcom.com>
Source record: 108855

I have a modified Kokasi 800 mhz radio. It has been modified to 900 mhz for operation in the 902 to 928 mhz HAM band. The problem is that I have very little information on it. It has been equiped with a Motorola Motrac control head. It was operational previously. I have tried to power it up with no success. When I apply power to its main + and - power lines and the lines at the control head for ignition connection etc, still no luck. If you might have info on this radio. It is a trunk mount unit, black with a large heat sink at one end and is very neat and modular inside. Each major functional module is in it's own seperate enclosed case.

Any help you can give would be very appreciated.

Randy

I attended the Central States Convention this summer in CS,Co. I did not attend the NF measuring. However, if the L-Band preamps were aimed at SETI, the 1420 MHz frequency is the hydrogen maser emmission frequey. Both the temperature and radial velocity of a distant hydrogen cloud can be measured at 1420 MHz by measuring the broadness of the emmission and the doppler shift from the laboratory reference frame emmission. It is felt that since many "intelligent" look-ee-loos at deep space will be looking at the hydrogen maser emmission. Therefore, its a good place for amateurs to look for possible radio emmissions from other "intelligent" aleins (?).

The Philips TDA7000 is probably the easiest way to do this - you just
need the one chip (plus some other components, of course).

For this range of power and frequency, a look at an article in May 1995 RF Design is in order. They have described in an article "High-Efficiency Power Amplifiers for 13.56 ISM and HF Communications", a two (plastic) MOSFET amp that puts out 400 W CW with 5 watts in using a 100 V power supply. Am thinking about building one for 160 for use when I don't want to turn on the big amp.

You might write Richardson Electronics, Ltd, 40W267 Keslinger Road, LaFox,Ill 60147 for a reprint and data sheets. The amp looks simple with no big headaches if you have some experience in homebrew. Suspect someone will have an article out in the ham mags on this soon....it's too good to overlook.

I am building a portable power source and want to build a voltage meter using a few LEDs. I figured I'd use some zener diode circuit. I want to start at 12.6 volts and work down to 12.0 volts. In other words all LEDs lighted when fully charged then to extinguish as the battery drains. I'd appreciate any help.

Thanks, Jeff KD6DHB

6050. Heathkit HW-8 on SSB?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-15 00:00:00 UTC
From: DICENSODJ%DFL@pcmail.usafa.af.mil
Message-ID: <4as7e3$nk9@usafa2.usafa.af.mil>
Source record: 108863

When cleaning out my shack, I exhumed my old HW-8. Hasn't had any voltage running through it in years. Nostalgia! As I played around with my HW-8, I recalled a relatively simple SSB oscillator module that 73 magazine did an article on maybe 2-4 years ago. Hmm...

Anybody ever tried to go SSB using the venerable HW-8 as a basis? Anyone got any suggestions or observations on the propsects of such a modification?

Thanks for any thoughts or comments.

6051. Temperature Compensating Tuning Diodes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-15 00:00:00 UTC
From: rst@tetrault.com
Message-ID: <rst-1512951604020001@squaw-d126.sierra.net>
Source record: 108864

There was a brief thread discussing the scarcity of info on this topic here recently.

I contributed the observation of the ARRL Handbook 95 circuit of thermistor bridges used to vary the bias of a tuning diode to act as a variable tempco capacitor.

Have found a pertinent Motorola Application Note AN-551 which specifically addresses temperature compensation techniques for tuning diodes. The material should be available from local Motorola office or from the RF Device Data Book Volume II, Q4/88, DL110, Rev 3.

Good Luck,
Bob T.

I don't know of any that would feed PC material.

>4. Is registration any better than what you would get with a laser printer ?

I can't see how they could be as good. In the Horz a laser should be near
perfect. In the vertical both have similar paper movement. Having used
both I find the laser usually seems more accurate.

>5. Any other ideas ?
The only direct print to PC board I have heard of is with a flat bed
plotter. Some have reported drawing directly on the material with
ploters. However my ploter moves the paper in one direction and the pen
in the other. It would seem that you should be able to put a pen in your
cnc drilling machine and draw using it with proper software. Is it a home
brew CNC drill or what. The basics of a plotter and a cnc machine are all
the same.

I'm probably totally out of turn (having not read the original article,
but would like to do so) but.... wouldn't it be pretty easy to get the amp
into a linear mode if it's based on FETs ... just bias the gates into the
linear region, or is there something more to it than that? It seems like a
high power solid state amp that runs off about 300V would be a really neat
toy (you could do good AC line isolation and not even have to worry about
the weight of a power transformer for 220VAC operation!)

6054. Re: How to add AGC to a Tube Radio?? (Swan 250)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-16 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <4a1_9512161331@mba.mba.org>
Source record: 108726

Apparently (I missed the original post) somebody acquired a
Swan 250 and wants to add agc to it, or something like that.

Somebody has already said that the rig has AGC. I assume that's
correct, because I can't imagine it not having AGC. On the other
hand, in the early days of the Swan rigs there were articles in
the ham magazines about adding AGC and/or improving it. The details
are fuzzy, and I'm not into searching right now. I'd say that
the very earliest Swan rigs must have needed improvement in the
AGC department. The later rigs, I'm not so sure. THere were plenty
of articles about modifying the Swan 250, but again I can't recall
the details so I couldn't say whether people at the time deemed it
to be lacking in good agc. The problem of the original poster might
be that it wasn't a good implementation (there were variations on
the 250 over it's life; the number remained the same but a letter
was added at the end), or that in his particular rig the there's
a problem in his agc that needs repairing.

Ah! Winter is here and the tubes are coming out of the closets.

For a vacuum tube receiver, AGC (and MGC) is implemented by ad-
justing the voltage on the control grid(s) of the IF amplifier and RF
amplifier stages. For the most part, pentodes (three grids) were used
for this function as the transconductance curve is more linear.
Variable-u pentodes like the 6AU6, 6BA6, and 6AK5 (my favourite) were
very widely used, so look for something like this in the radio. The
AGC voltage is derived by rectifying the audio, and then conditioning it
as required to achieve the desired results.
There were a number of variable attack- and delay-time AGC
circuits in the ARRL handbooks of the 60's and early 70's (vacuum tube,
of course) and undoubtedly solid-state versions in later years. You might
want to stay with vacuum tube solutions because of the voltages. And, of
course, because you are a purist.
You <ARE> a purist, aren't you (HI)?

Hi there -

I have developed a small keyer kit - called the uKeyer
(microkeyer) It is a complete iambic micro keyer on a 1" PCB -
designed for use in Homebrew equipment.

Look out for it in your local magazines - will be reviewed in
RadCom in the UK - and hopefully in QST RSN.

It boasts the following features:

5 to 50+ WPM
Low power consumption (1uA in standby)
Small size - 1" (25.4mm) square PCB
TUNE button for 10 secs keydown
stored CQ CQ DE <call> <call> AR PSE K at the press of a
button
Dot/Dash memories
low cost - (£20.00 + 1.00 P+P)
for the kit (£26.00 + £1 P+P for a built PCB.

THIS IS REALLY AN ADVERT - but thoguht you all might like to
know about it...

Email 101454.3715 @ compuserve.com for more info - ta

A couple of hams that I work with have been kicking around the notion of building a direct conversion receiver using a quadrature NCO for the local oscillator, and a dual input DSP to perform the phase shift and audio filtering functions. Seems that a very high performance unit could be built with extreme reproducability and reasonable cost.
A couple of threads on this topic have started and fizzled here, but I'm wondering if anyone would like to discuss forming a 'virtual project team', either on this group, or some other Internet vehicle to try to pull this off.

>ag722@ccn.cs.dal.ca (Chris Findley) wrote:
> Also, and most important: What can I use to mask
>large areas of the board with??? I am familiar with the photo etch....

I used to use fingernail polish or fingernail hardner. Just paint it on
and let it dry. I tried using tape before but I usually had the edges
loosen up, undercuting the edge and any tape joints. I expect that
something like Testors Enamel model paint would work too. Or probably
any old house paint or maybe even spray paint. The hardest part is
getting some of these materials off the board when done! Use a solvent
to loosen it up. I used to put the fingernail polish on thick and run a
razor blade under it for removal. Always finished up with a light
sanding anyway.

I'll also agree that getting the spray resists to work was very hit and
miss, mostly miss. If you want to spend some time with graphic arts,
the old silk screen techniques are still the best for large quantities
of boards at home. Some of the graphics arts films for silk screening
might also work as a direct application photo resist for the board. What
looks like the most promising technique for one or two boards at a time
is the laser print plastic films. That assumes of course your printer
can do the graphics or the local copier can make a real 1:1 print.
I bought some of the film a few years ago but haven't used it yet so I'd
be interested in hearing other peoples experiances.
Merry Christmas!

There are two circuits in the W1FB QRP notebook which provide for DSB generation. I imagine you could put such a circuit before the P.A in the HW-8. Very simple, a 741 and a few parts.

If memory serves, the 6AU6 and 6AK5 of the above trio are sharp cut-off
pentodes. Application of AGC to these tubes may result in a harsh AGC
characteristic and some interesting overload effects. It can be done,
however.

Back in the days of the Swan SW140/SW120 AGC-less tranceivers the guys
used to full-wave rectify the secondary of the audio output transformer
and apply the negative voltage to an ad hoc AGC bus connected to the DC
returns of the i.f. amplifier control grids. It sounded harsh, but
worked well.

Somewhere in QST about ten years ago there was a circuit for a Class C final using an IRF530 power FET running on 24V. With a good heatsink the author said it would do 50 watts, for less than a watt input. The circuit was awesomely simple, and if you give me a day or so I'll dig around and find the exact issue. It wasn't a feature article; it was in Technical Correspondence.

It could be exactly what you're looking for.

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

The CCI amplifier kits are good starting points. All on board parts, PC board included... you gotta supply enclosure, heat sink, switching, and output filter. I have the AN762 design -- 140 watt max -- waiting to be built. All based on Motorola design bulletins.

6076. Varicaps for Texscan Analyzer?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-16 00:00:00 UTC
From: Ian G3SEK <G3SEK@ifwtech.demon.co.uk>
Message-ID: <883105248wnr@ifwtech.demon.co.uk>
Source record: 108872

Help, please, to repair a dead Texscan AL-60B spectrum analyzer.

I'm trying to locate a replacement source (or at least some data or equivalents) for the VCO varicap diodes, type VAT51E.

It would be worth replacing or rebuilding the whole VCO, just to get the analyzer going again, so are there any other sources/ideas for a VCO that covers the whole octave from 1.0GHz to 2.0GHz?

>of the IF stages based on the strength of the signal at the detector.

I'm not familiar with the 250's specific AGC circuit, but older rigs
often didn't have the control range we expect by today's standards.
Maybe it's not working. Is the S-meter moving?

_____________________________________________

1.0 What is BASIC Stamp ?
-------------------------

This is being written for people who have no idea of what a BASIC
Stamp is...

BASIC Stamps are small reprogramable single board computers (SBC)
that run BASIC programs and are made by Parallax, Inc. in US. At
first glance, they may seem fairly minimal - and in fact, they are.
But with software that fully utilizes all available hardware, the
Stamps give you powerful features - without the cost of hardware.

Their low cost and simplicity make the Stamps perfect for many
prototyping and control applications. It's suitable for electronics
hobbyists as well as electronics professionals in many different
areas.

Typical application areas for BASIC Stamp's are...

- General electronics
- Home automation
- Robotics
- Mini PLC
- Education
- Prototyping
- HAM related applications
- Special effects in films
```

- Industri control
- Geological instruments
- Computer peripherals
- Scale model hobbyists

As an talent engineer and technical writer expressed it...

- BASIC Stamp is the 555 of the 90's !

1.1 What is L.O.S.A all about ?

I started to compile L.O.S.A because I know there are lots of great ideas and many problems that are solved with the BASIC Stamp and the main purpose of this list is to get an idea of what other people are using their BASIC Stamps for and maybe get some inspiration or hints.

Remeber it's up to all of us if this list are going to be any good and I'm looking forward to receive a description of your application.

1.2 How can I contribute to this list ?

If you have done something with the BASIC Stamp (big or small) that you are willing to tell others please use the form given below and write a short description, nothing fancy is needed just a simple explanation. If you have source code to share that's even better but it's not necessary.

Then e-mail the form to:

cj@algonet.se

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill in the L.O.S.A form on the Web-page...

http://www.algonet.se/~cj/losa.html

==========
Title : Robo-Cat [# 001]
==========
Date : 950807
Author: Gustavson Guy W.
E-mail: GWGUSTAVSO@mpg.norstan.com

Stamp model : BASIC Stamp Rev. D
Code available: N/A
Filename : N/A
URL : http://www.winternet.com/~bigfoot/cat.html

Description :

My cat, Kesha, was recently diagnosed with Heptic Lipodosis. Or
"Fatty Liver", basicly what this means is that for some reason he
stoped eating and his liver started converting body to useable
sugars. The fat deposists biuld up in the liver and cause severe

liver damage. Because the liver isn't working well the cat feels crappy and wants to eat even less. The treatment for this disease is to run a tube down down the cats nose into his stomach, or a PEG tube through the abomine wall into the stomach and feed the cat a liquid diet this way.

I love my cat, but I can't be there every three hours to feed him through the tube for a month. Something about work and deadlines and such. So I went to a local supplus house and got a tiny motor driven pump, a case, some switches, a micro switch, ect...

The micro switch is mounted such that the switch trips for every rotation of the pump shaft. The stamp turns on the pump for on a single rotation at intervels programable from the controll switches on top. An alarm buzzer and LED flash if the pump fails to run for any reason. The unit is programable for 9 differents deleviery rates.

Now he gets a slow continuious feeding and he seems to tolerate this better than the 100ml feeding every three hours.

==========
Title : Logic Rudder [# 002]
==========
Date : 950812
Author: Christer Johansson
E-mail: cj@algonet.se

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : LRUDDER.ZIP
URL : http://www.algonet.se/~cj/filelibrary/BS1-IC/

Description :

Many of the new and very realistic flight sims available today needs rudder to let you get full control. This one uses a digital pot from Xicor (X9104) and 10 other components. Connects to a standard IBM-PC game port and power is taken from the port.

It uses two micro switches for controlling the rudders left or right and to indicate when rudders move there is a red LED that lights up when you press the micro switches and to indicate center there is a green LED. If you press the both micro swithes the rudder will automaticly return to center position.

There is a trim pot to set the desired step rate from slow to very fast and the Xicor pot has 99 steps wich gives a fair resolution.

==========
Title : Interfacing MAX186 8 channel 12bit A/D [# 003]
==========
Date : 950925
Author: Helmut Fligge

E-mail: h.fligge@asco.nev.sub.de

Stamp model : BS1-IC
Code available: YES
Filename : N/A
URL : N/A

Description :

This Program interfaces the Stamp1 to the MAX186 A/D converter. Via RS232 2400bps the stamp is asked to measure channel numbern. After conversion the result will be returned to the host computer as an ascii string (0 .. 4096). Conversion rate is about 4 measures per second.

==========
Title : Scrolling LED Sign [# 004]
==========
Date : 950926
Author: Bob Blick
E-mail: Bob_Blick@redwoodfn.org

Stamp model : BASIC Stamp Rev. D
Code available: Maybe sometime
Filename : N/A
URL : http://www.execpc.com/~bblick/stamp.html

Description :

Scrolling LED sign, 35 super-bright LEDs in a 5-by-7 matrix in the prototyping area of a Basic Stamp rev D. A scrolling alphanumeric message moves one pixel at a time, just like real scrolling LED signs, except this one only displays one full letter or portion of two letters at a time as the message moves by.

==========
Title : Tone Decoder [# 005]
==========
Date : 950926
Author: Bob Blick
E-mail: Bob_Blick@redwoodfn.org

Stamp model : BASIC Stamp Rev. D
Code available: Soon
Filename : N/A
URL : http://www.execpc.com/~bblick/stamp.html

Description :

Listens for telephone touchtones, displays phone numbers on LCD screen and echos them out RS-232 port. Circuitry fits in prototyping area of rev D Basic Stamp:

Microphone preamplifier, touchtone decoder IC.

==========
Title : Pager [# 006]
==========
Date : 950928
Author: Don McKenzie
E-mail: donmck@tbsa.com.au

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : PAGER.BAS
URL : ftp://ftp.parallaxinc.com

Description :

This program for the Basic Stamp is used to monitor 4 hardware signals. If a change takes place, (after testing for a false trigger) then a cheap 2400 baud MODEM is used to dial into a Telecom Alpha-Numeric pager. It leaves a message which consists of a 2 digit I.D. (01 to 99) followed by the 4 signal levels of pins 3 to 0.

Status of the signal levels message: 0=Low, 1=High. EG: "011110" means Unit "01" has pins 3, 2, and 1 high, and pin 0 is low.

A "Ring-In" feature is also included. By ringing the MODEM for a short period, then hanging up, the Stamp will dial your Pager and report the current hardware status of these four signals.

This program uses about half of the available memory, so if the user wishes to add enchancements such as "Multiple Ring-In's" say within a minute, for a command selection, there is plenty of program space left.

==========
Title : HexWalker Mobile Robot [# 007]
==========
Date : 950929
Author: T. R. Thornton
E-mail: mandtsys@ix.netcom.com

Stamp model : BASIC Stamp Rev. D or BS1-IC
Code available: YES
Filename : WALK.BAS
URL : N/A

Description :

HexWalker is a six legged mobile robot that is controlled by a BASIC Stamp or BS1-IC, and driven by three servo motors (similar to Futaba S148). It is the simplest walking machine architecture that can walk forward, backward, and turn left or right.

```
=========================================================================
Title : Robo Bug [# 008]
=========================================================================
Date : 951003
Author: David Novick
E-mail: dkn@cimar.me.ufl.edu
-------------------------------------------------------------------------
Stamp model : BS1-IC
Code available: YES
Filename : N/A
URL : http://www.me.ufl.edu/~dkn
-------------------------------------------------------------------------
Description :

Using two stamps, a robot with six legs (2 degrees of freedom each)
was able to walk and turn (at this stage, not very gracefully).

=========================================================================
Title : EXPBOT Robot controlled by Stamp [# 009]
=========================================================================
Date : 951009
Author: Marvin Green
E-mail: marvin@agora.rdrop.com
-------------------------------------------------------------------------
Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : EXPBOT.BAS
URL : E-mail author and he will send it
-------------------------------------------------------------------------
Description :

This program allows a cool robot to move abound a room in search of
light. Like a moth. Simple program changes can dramatically change
the robots behavior.

=========================================================================
Title : Andrews Ever Evolving Lego Robot [# 010]
=========================================================================
Date : 951119
Author: Andrew H. Hochheimer
E-mail: softarts@ciaccess.com
-------------------------------------------------------------------------
Stamp model : BS2-IC
Code available: YES
Filename : N/A
URL : http://www.wincom.net/~softarts
-------------------------------------------------------------------------
Description :

Currently the robot can only navigate to the brightest light source
in a room. It's current operation mode has four major steps: - Scan
a 180 Degree Field of "Vision" taking light level readings, and
determining the brightest direction of light. - Decide if it needs
```

to turn left, right, or continue moving forward. - Check for collision with an object while moving, if a collision occurs, display the total travel distance on the display - Move forward for 1.5 Seconds and then repeat the process.

Currently I am using Two Futaba FP-S128 Servos (any RC Car Servos would work) one to sweep it's "sensors" form left to right, and one to "stear" the robot.

You can see pictures and more information on my homepage, just follow the lego robot link.

==========
Title : Factory Monitoring System [# 012]
==========
Date : 951120
Author: Paul Willemse
E-mail: pjwill@merlion.singnet.com.sg

Stamp model : BASIC Stamp Rev. D
Code available: YES
Filename : N/A
URL : E-mail author

Description :

The system presently consists of 4 Basic Stamp units. Each monitors up to 5 inputs. The inputs are 'digital' (switches) and/or analog (temp, airflow, current, etc using commercial sensors). All stamps communicate the results via serial mode to a Macintosh (Yes a Mac!) where the results are graphically displayed and monitored. Alarms are set for certain conditions.

The transmission is simple, one way only. Each stamp sends the info at a 'random' interval not exceeding 2 seconds. The message format is fixed, the Mac will throw away any conflicts in case two or more stamps transmit at the same time. BTW this happens very seldom. The max time any stamp can be 'absent' from the chain before an alarm is raised is six seconds (failure, transmission collisons, etc). This is controlled by the Mac.

The 'system' is presently in beta test, the client wishes to expand up to 20 stamps. At that point we will likely use the BS1-IC or BS2-IC on custom boards located around the facility.

Code is available upon request (e-mail) partial, some is proprietory to my client.

Title : Wave to the Cats/Desk Temperature [# 013]
==========
Date : 951121
Author: Paul Haas

E-mail: paulh@hamjudo.com

Stamp model : BS1-IC
Code available: Yes
Filename : See web server
URL : http://hogwild.hamjudo.com/cgi-bin/stamp

Description :

The Stamp has a serial connection to web server, a cardboard hand, a servo motor to move the hand, and a DS1620 thermostat chip to measure the temperature. The web server can request the current temperature or start the hand waving. See the web page for the source code for the temp and the web server.

It's mostly useless. The cats ignore the hand. A few people find it entertaining.

==========
Title : Gamer's Die Roller [# 014]
==========
Date : 951122
Author: Larry Tremblay
E-mail: ltremblay@domus.com

Stamp model : BS2-IC
Code available: N/A
Filename : N/A
URL : N/A

Description :

The Gamer's Die roller is a little thing I am putting together as my first Stamp Project. The Roller allows cumulative rolls of n dice up to 256 sides, so long as the sum does not exceed 99,999,999(!)

It uses two 74HC161 4 bit counters cycling at 1MHz to draw random numbers off of. Input is achieved via a Grayhill model 38 keypad and a 74C922 keypad decoder. Display is on a Siemens PDSP-2111 8 character smart display (5x7 LED characters) fed by two 74HC164 serial to parallel shift registers cascaded so I can use Shiftout to feed 16 bits of control + data off of 2 pins.

The code is very simple, the most exotic part being the random number generation. In a nutshell, it is:

Begin Loop
S = 8 bit number drawn from the counter (random)
if S < (255/N) x N (integer divide, N is number of sides on die)
exit Loop
End Loop

This gets (pseudo) random numbers whose average is not skewed downwards by the counter's max of 256 (i.e. a 100 sided die is not affected by the extra 56 in the count maximum)

Using gamer's dice notation, (5d6 = sum of 5 six sided dice, 3d10 = sum of 3 ten sided dice), the user can input whatever combination they wish, including just 'd6' for one six sider. The keypad I have has removeable keycaps with legends, so I have 0-9 plus 'd' and '=' on them.

As noted earlier, since I am using an 8 bit counter, the maximum die size is 256, although that could be fixed easily by sampling two, three or more times for each die.

Anyhow, that's it. When the code is done and debugged, I'll be happy to e-mail it to any who want it.

```

6079. Re: Phasenoise-FFT-offline

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-17 00:00:00 UTC
From: rrrath@aol.com
Message-ID: <4b15n9$c21@newsbf02.news.aol.com>
Source record: 108742

Hi,

I have tested two shareware pgms with impressive dynamics which are much
slower then the freq4 or digitize:

a)hpwfft1.zip or hpwfft2.zip (more or less same, 1 MB)
WINDOWS, for soundcards and BB7805 AD or an external
20bitAD described in German ELRAD.
in Compuserve: midiforum and hamnet;
ftp.ix.de/pub/elrad area 20
or http://ix.de/el
More or less offline, impressive dynamics, up to 130db, in help file
some
sample screenshots are included. FFT dsiplay and:
table with THD and SN, offset values etc
Very large FFT with pay-version possible,
My PAS 16 revealed: 2th harmonic -76db, 3rd -90db.

c) cheaper: NEW cooledit vers.152
cool152.zip on cica-sites, compuserve, aol etc.
allows recording and then FFT up to 120db dynamic,
pgm also usefull for wavegeneration etc.

d) Errol Williams has written a FREE tool for wav-files
WINDOWS; incl. spectrum, voiceprint, 3d-spectrum
not best dynamics, but very simple and versatile for recorded
signals (e.g. shortwave etc)
wavwev.zip (52K) : ftp.tpoint.net/windows/sound

?? anybody knows better pgms?
?? anybody adapted for Zoom-FFT

73s and Merry Xmas from Munich
Robert DJ0RA, OE5RRL

ps: please use after dec.29th my CIS ID: 100626,3217@compuserve.com

6080. Re: Phasenoise-CHEAP-FFT-online

Source record: 108743

Hi,
Conventional analysers and panadapters are very slow if used for narrow spans.

I have been experimenting with some pgms for FFT with soundcards (e.g. from Simtel , Cica site), but IMHO the following pgms (FREE!!) are the best:

a) freq4.zip (134KB) DOS from Phil VanBaren
on many sites, or simtel/sound
supports 16bit mode of Pro Audio Spectrum 16 and PA Studio 16,
other soundcards only in SB 8bit mode.
With PAS 16 about 75db dynamic, very useful online change of parameters very fast, also freeze, screenshot possible.

aa) the new freq51a.zip(515K) is more or less the same, somewhat less stable?
but includes version for LINUX and supports Logitech Soundman as well as
cards with VESA AI BIOS.
http://schaeffer.eecs.umich.edu/~phillipv/signal ..also screenshots as well as sonogram.

b) digitize from Matt Park--WINDOWS
dig12b1.exe ftp.transend.com/pub/users/mattpark
less dynamic ..60db, but useable with all soundcards
Author has written it for a friend --panadapter and described in:
Aug.1995 Circuit Cellar Ink, The Computer Applcation Journal

c) A fellow ham and spectrumanlyserdev. was quite impressed by a simple FFT solution at a RFexpo about 1 1/2 years ago,
very small company, owner from India,
offered DEMO disk and brochure as well as soundcard with add. screening.

Unfortunately said Om has lost disk and address
Anybody know??

Any other good and cheap pgsm known??

-see my further info about offline pgms

73 and Merry Xmas from Munich

6081. Printing to PCB material from a laser printer

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-17 00:00:00 UTC
From: timj@solo.pipex.co.za
Message-ID: <30d42a95.101198859@news.solo.pipex.co.za>
Source record: 108744

Does anyone know of a simple way of getting PC board artwork from a laser printout to the PCB material for etching?

If it were possible to feed the PCB material directly through the printer that would be perfect but it isn't. Not on my Laserjet 4L at any rate, as far as I know.

I've tried printing to glossy paper and then ironing the image onto the PCB but without much luck. Maybe I'm using the wrong paper.

ANY hints, tips or ideas would be most welcome.

Thanks.

Drew:

I have to agree with Kerry on the 40 and 80 meter QRPers. I have built the 80 meter job and it worked great. I had a long contact too.

For simple kits you might want to look at Ramsey Electronics. I built several of their kits and with the exception of being short of parts in the list, whioh they replaced at my concerned request, the units worked excellent.

Good luck!

Source record: 108746

Thanks for all your help, meanwhile I managed to build up a parallel resonator. From some 'old' equipment (RF-sweeper + scope) and a 'Magic-T' I built up some kind of device you suggested. Seems to work fine.
One last (?) question:
the whole trouble started when I tried to change from series resonators to parallel resonators in order to be able to tune externally and to hold losses along the line low. Using just a coil and after n*lambda/2 a series C + paralle C would mean high VSWR and so high losses. Now what if I put the coil and the series C at one end, the matching parallel C at the other end of the line ? This would be a 'normal' (considering our probes) series-resonator, so more used to me. But would this also mean high losses along the line ? I think that the high voltages at resonance (that are responsible for the great losses, if just the coil is at one end) only occur between series C and coil, so that they would NOT be seen on the line in this concept. Am I right with this idea??

Hoping for your patience is

Thorsten

LM3914 drives 10 diodes linearily with the input voltage. Works down to
5 V I think and as high as 18 V (Vsupply). About $3. You can choose
between single diode or staple display by manipulating one input
pin. I think a sample circuit is in Radio Electronics April 92
as part of an LED based oscilloscope display.

Hi Paul

I ran across the same problem last year!

The 16-pin DIP is the charger circuit itself. The numbers stamped on
the package are proprietary and not easily cross referenced.

However, I was able to obtain the chip from an ECG component supplier.
The replacement chip was unmarked, however, my original chips were
marked, UC3906 and UC2906 mfg. by Unitrode.

Apparently, the pin-out for all 16 pin charger chips are identical.

Sorry, that's all the help I can give.

Gary

>get started.

Home again. If you have access to older QSTs, get the November 1989 issue, and look at "Technical Correspondence" on Page 38. A longish piece on power FET amps follows, which addresses weaknesses in a Doug DeMaw design published in the April 89 QST. On page 40 is the IRF530 amp I mentioned in my earlier response. The text says it can output up to 50W at 14 Mhz with as little as 1.5W of drive. "Similar output is available on 80M driven with nothing more than a crystal oscillator." There's some math to be done in working out the matching networks, and probably a little cut and try, but it's awesomely simple and I hope to put one together at some point.

Well, not quite that sophisticated, but I've been trying an old Ten-Tec PM3A transceiver (DC, 20 & 40M) feeding a Radio Shack DSP40 for audio amplification and selectivity. The combo works reasonably well, but the lack of AGC action in the Ten-Tec makes it awfully hard to hit the preferred input level "window" of the DSP40. I suspect you'd want to work out these AGC issues before getting too committed to this scheme.

I'm not sure what a DSP40 is, but I assume that it's some sort of audio filter. Of course, the problem with audio filtering in a DC receiver is that it does nothing to reject the image frequencies. A dual DSP at the quadrature outputs of two mixers would, theoretically, perform near perfect unwanted sideband cancellation. In addition, the DSP program could perform a compound AGC action by performing limited AGC action in software, and also drive a hardware gain reduction circuit at the RF input for increased dynamic range.

Source record: 108755

Hi,
in the previous discussion regarding the HP8640B was mentioned.
Also the 3585 is still quite expensive.
Personally i�m using a Marconi TF2370-2373 or self built 10,7MHz unit:

mixer, filter, TBA120, diff amp driving Xtal discriminator at 10,7 MHz,
followed by lownoise Opamp.

Marconi has published a similar approach about 10??years ago, used
for their own test of synthesizers etc.
mixer, lowpass, lownoise 1,5MHz IF amp with discriminator, then TF2330
waveanalyser.
Indicated measurement limit:
100Hz offset 115db
1 KHz 140db
10KHz 153db
Advantage: no phase lock required, thus alos for free running osc., as not
so sensitive at low offsets thus for old valve osc. with 60Hz sidebands.
Disadvantage: insensitive very close to carrier.

"Marconi Instrumentation Vol 115, no.6,
"Measurement of phase noise in signal generators", D.P.Owen, pp.117-122.

PA0JZ has described in the Dutch Ham magazine VERON may-july92
a cheap doit yourself unit:
mixer (MD108), lownoise preamp with BC149C, amp NE5534, then
2 spot filters at 1 and 10 KHz with 4 opamaps aech and
1 100KHz LC-filter.
2 opamps for phaselockcircuitry.
Measurement limits wtih Xtal osc:
1 KHz offset 140db/Hz
10KHz 165
100KHz 170db.

Idea: why not use FFT with a soundcard at output
-see seperate message.

>the same.
> Garry WB0NNO

True enough, but my CNC drill is a NCed Sherline mill, and it is slooow. I would have to figure out a way to keep the pen from drying out. The main reason I would like to use a ink jet is I want 10 mil lines with 10 mil spacing. I have been able to get this with a laser printer, but with the registration problems I mentioned before. I don't think I can get this kind of resolution with a plotter, the lines would bleed together.

hi all
anybody done work with a tait t520 that uses a multi channel
swithching unit it comprises of 2 x bcd's feeding the board where the
diode matrix board was
the 2 chips {14/16 devices forgot which} are missing hence i cant
dissasemble the chips for the programme
A:have you got any info on the chips
b:have you got any info on the programme that goes into these chips

i believe that they are ttl proms ie as used in the mx290 series etc
any help much app
73's de laurie laurie@sdschool.demon.co.uk

I like the NN1G designs (there are several, all are superhet transceivers with VFO control on tx and rx). You can contact the inventor, Dave Benson, NN1G, via e-mail:

bensondj@aol.com

I've built three of his rigs, and like them all!

>idea??

It all depends on the coil (and sample, to the extent that it modifies the coil electrical characteristic, e.g. saline sample). A typical setup might be 100 nH, 1 ohm in the coil. At 100 MHz, this is 1 ohm resistive, 63 ohm reactive. No matter how you adjust it with a single component, you will have a very high SWR on the line.

The losses (outside of the coil and sample) are actually caused mostly by the CURRENT in the line, not by high voltages, unless you have some undesirable materials near the high voltage points.

I find that a useful way to visualize the effects of the external circuit is to imagine the magnetic fields associated with this circuit. Energy is stored in the magnetic fields. What you want is for most of the stored energy to be inside the sample, in order to have a high sensitivity. Thus, any conductor with high current and large size, which stores a correspondingly large amount of energy, will detract from the probe performance.

Your chance to get the PIC-1 programmer at our special introductory pricing is running out! This special pricing will end December 31, 1995. Don't miss your opportunity to purchase our PIC programmer at this special price. Call us today to place your VISA/MasterCard order!

This is the same popular programmer you saw mentioned in Electronic Products, MicroComputer Journal, Electronics Now, Nuts and Volts, and Popular Electronics. Hurry, get your order in today to guarantee the special pricing on this incredible deal!

To summarize our pricing:

* PIC-1 KIT $29
* PIC-1 Assembled/Tested $49
* PIC-n-GO KIT $39
* PIC-n-GO Assembled/Tested $59
* ZIF upgrade for above programmers $11
* additional PIC16C84-04/P with purchase of PIC-n-GO Package $7

ALSO AVAILABLE:
* 40/28 PIN DIP Adapter Assembled/Tested $25
(includes ZIF Socket for programming 40 and 28 PIN PICs)

THIS SPECIAL OFFER WILL END 12/31/95! ACT NOW! VISA/MC Accepted!

Please include $5 shipping/handling for orders inside North America, $10 outside of North America.

You may place your VISA/MasterCard order by telephone at (513) 574-7523 or by fax at (513) 574-4245 between 9AM and 5PM EST.

Your personal check or money order is also accepted.

6103. Re: Drilling PC boards Simple PC Board Drilling Machine

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-18 00:00:00 UTC
From: rmc@chem.psu.edu
Message-ID: <4b4b6n$10jb@hearst.cac.psu.edu>
Source record: 108766
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics,sci.electronics.cad

Drilling PC boards has always been the most tedious part of any homemade pc board, so a solution to get rid of the missed holes and inaccurate holes is a lifesaver in our shop. This article will describe the basics of our machine, and hopefully enable other people to build a machine of their own.

The theory behind the machine is that stepper motors can be controlled by a computer and told
to move. This machine uses the computer printer port, as it is very inexpensive and has enough
outputs to do the job easily. The outputs from the printer port are latched into IC latches,
and the proper latch is strobed to move the motor needed.

If some stepper motor theory is needed, here are the basics: a stepper is a permenant magnet
motor with no brushes; it is made to move by energizing different windings in a sequential pattern. This pattern is well suited to do with a computer, as it is simple and repetive.

The above basically covers the electronics for the machine, an interface from the computer to the motors, and a power supply for the motors are the only electronics required for the system.

The mechanical aspects of the machine can be more involved, but, in essence, consist of assembling two axes (the X and Y axes), with one of the two carrying a third (Z axis), which
in turn holds a motor tool.

We have built several versions of the system, the original using the ground rods and stepper
motors from scrap dot matrix printers along with purchased aluminum supporting material, with
another using the actual assemblies from the printers mounted on a piece of wood, one horizontal
and one vertical, with the vertical axis holding a z axis and it in turn holding a drill.

Up to this point, I have not mentioned that these machines have z axes as well as x and y, what this means is that this machine is also capable of doing 3-D surfacing, which differs from
some of the commercial machines used for drilling in that their z axis is normally a spring loaded solenoid, while this is a machine with as much z axis travel as is required.

This is the hardware aspect of the machine, while it takes some time to build it, the majority of the time in our project was devoted to writing the Quickbasic programming. This program is designed to find the pc board holes, which it can find in ASCII, Orcad, and most other popular pc board programs that can output an x and y pair, and read them into and array.

It then takes this array and displays it on the screen as drill holes, and asks to align with
the smallest and largest x,y hole pairs, which it displays in red. After this is completed, it

sets the drill depth and drills the board. The program can be paused if there are problems such
as a broken drill bit, etc. (By the way, our machine wears out the bits before it breaks them,
try to do that with a drill in a press!).
The software has also been written to interpret most of the basic HPGL commands, so it is able to engrave things that have been plotted. We have also used it with great success to draw
words and lettering on front panels with a plotter pen fitted in a holder.
With all of this said, to draw the schematic on here would not be easy, nor could I include the software, since my boss has a lot of time wrapped up in it, but if enough people were interested, maybe we could offer the schematics, pc board?, and software for a nominal fee. The
actual machine construction is easy for people with a drill press, maybe a hacksaw, and lots of
patience, but it can vary depending on the type of printer you use and the way it was assembled.
If I try and come up with a drawing of our machine, are there preferences for the format I use, eg. DXF, Bitmap, etc.?
I will try to work on the design some more during my spare time, if you're still interested,
post here or e-mail me, especially if you would like to see a software, schematic and maybe pc
board kit. We need to see how much interest there is in this project to decide whether to make
pc boards, clean up the software, make drawings, etc.

Yes, that could be a problem.

>2) is diamter of the material used to build the coupling
>loop (not the loop diameter itself) a critical dimension?
>do I need to recalculate the coupling loop diameter?

No, except for losses or unless the conductor diameter starts to become
large compared to the loop radius.

>3) the only connections where I am suspicious of resistive
>loss are to the VVC. Since I can't/won't weld to the VVC,
>the copper pipe is flattenned and bolted down to the VVC
>using plated screws, mating to plated surfaces, with

>of loss?

Everything can be, because the current is so high! If the loss is
concentrated in one small are it will get hot. Are the connections getting
hot or warm?

>4) any experience with gamma feed v. inductive?

Either will work fine, I use inductive feed on my small loops. On one
commercial application I used gamma feed to reduce complexity.

I'd get the loop away from everything else and try again, or rotate the
thing 90 degrees and see what happens. When I lay receiving loops flat
over earth on 160, they just about go dead. Maybe the stucco screen is
providing you with that problem?

Hello dear OMs!

I'm a newcomer in amteur radio, and I am fascinated from digital communication especially on
short wave. So I thought it may be the best solution to write a message in the internet, maybe
there will be someone who can help me:

1. I'm looking for all kinds of rtty, packet and amtor mailboxes. I'm interested in the callsigns and the frequencies. (in amtor: call & selcall!)

2. I'm looking for the frequencies of fax- stations for receiving all kinds of fax, especially
wefax.

3. I'm looking for the frequencies of all kinds of commercial transmissions, which are not encoded.

4. I'm running a pk232 mbx with pc-pakratt software. I'm looking for a PC- software, which is
able to decode the numbers which are transmitted in the weather reports on rtty, and a programm
which decodes the navtex code.

I hope that there will be somebody, who can help me, and send the message via e-mail to me.
My call is DL2MHL (I'm not QRV in UHF or VHF packet)

Thanks already now, and best 73

I wish you a good 1996

Stephan DL2MHL

: Have you considered using television network burst processed for an
: accurate source. Any time your local t.v. station is broadcasting
: network feeds, their 3.57954545 signal is good out to upteen decimal
: places. About 10 years ago I phase locked a crystal oscillator to the
: crystal of a small solid state color receiver on the bench. Divide by
: 88 and multiply by 63 and you've got 5.000000000 Mhz. Turns out our
: local NBC affiliate kept the station locked to network black-burst
: even while they were originating locally . . . made for a rather
: simple way to get lots of zeros behind the integers . . .

: Regards,

: Bob, K0DYH

I believe you will find this not valid anymore. Since every local station
started using local syth'ized systems.

We used to do this also but hat to stop and go back to WWVB.

YES! And the loss would account for lower Q and failure to
match correctly, as mentioned above. You should be able to
get the published Q values with proper construction and
installation.

6109. Transmitting loop near miss

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-18 00:00:00 UTC
From: Dave Curtis <david_b_curtis@ccm.sc.intel.com>
Message-ID: <4b496l$eb@inews.sc.intel.com>
Source record: 108772

This weekend I did my first rf tests on a homebrew transmitting loop. It's acting a little wierd, and I have some troubleshooting questions.

Here's the scoop:

20 foot circumference loop, made of 3/4" water pipe in an octogon.

15KV 10-350 pF VVC.

Feed is a 38 inch circumference loop. (inductive feed, like QST article from last year, not gamma feed, as in antenna book). Loop is made of 1/4 inch copper tubing.

Given this design, I expect to have acceptable performance on 40,30, and 20M, and inefficient performance on 80M if I were to add a ground plane.

For testing, it is installed with the bottom about 30 inches off the ground. It is tie-wrapped to my deck. It is about 4 feet from the house wall and about 3 feet from a fence. It's a crummy location to be sure, but I have very limited space for testing (or anything else, for that matter).

Questions:

I get sharp SWR dips on all bands 80-20, so it does tune. I just never see an SWR below about 4:1 Also, it seems to be more broadband that I would have suspected. As measured by an Autek RF-1, it shows Z of about 40 ohms, max, at the tuned frequency. (I know, 40 ohms ain't 4:1 -- haven't figured that one out. Of course, nobody would confuse my instruments with an NBS secondary standard...)

1) could coupling to near by metal be causing low Q and this much loss? house and fence are stucco walls, so probably have masonary wire in them. Roof also has copious amounts of metal flashing, etc under the tiles.

2) is diamter of the material used to build the coupling loop (not the loop diameter itself) a critical dimension? do I need to recalculate the coupling loop diameter?

3) the only connections where I am suspicious of resistive loss are to the VVC. Since I can't/won't weld to the VVC, the copper pipe is flattenned and bolted down to the VVC

using plated screws, mating to plated surfaces, with liberal amounts of penetrox. could this still be a source of loss?

4) any experience with gamma feed v. inductive?

I don't have a good measure of the antenna's efficiency, but subjectively speaking I'd say it sucks. Only a few loud signals found on any band -- I could not copy signals that other locals could. Made a couple of Q's and got lousy (although sympathetic) signal reports.

Thanks es 73,
Dave NG0X

Probably the most sophisticated QRP kits are the ARK-series (ARK-40 is 40 meters, ARK-20 is 20 meters, etc.) by S&S Engineering. They're frequency synthesized cw transceivers, with an xtal filter, audio filter, digital frequency selection, and built-in keyer. They're built like a tank, with extremely high quality innards. Not for beginners, however.

I have a couple of Ramsey kits that run great on the battery, but when I try to hook them up to a power supply they don't work as well.

My CW-7 keyer sounds like a strangled cat, and my VOX switch kit is always on.

Both work perfect with a 9V battery.

The CW-7 is hooked up to 12vdc power supply and the VOX is hooked up via a 7808 regulator.

Any suggestions?

de KE6LBX

Just to confirm this, I have used a vectorscope and video waveform
monitor to compare sync and color timing of network feeds via satellite
to the same feed retransmitted by local affiliates (San Francisco) and
have noticed that they are NOT phase stable with respect to each other.

Getting a satellite receiver and using the direct network feed might be
one idea. Short term stability would be good, long term stability will
be subject to daily satellite dirft in space. You can get very good
NBC reception from the Satcom K2 satellite with a 4ft. dish. It would
be interesting to compare its burst with a real standard.

Can anyone help me??

Do any of the major semiconductor manufacturers make an off-the-shelf
IC which operates as a low power FX transmitter? You know, the sort
of thing one might use to build a cordless baby alarm or bugging
device.

Thanks in advance for any info!

There are special films made exactly for that purpose.
One of the best is called PnP Blue, It's a little over
$1 afor an 8.5x11 sheet and does a pretty good job atleast
on my Laserjet IIP.

I've found that a single transparency is not dark enough. Hold it up to a light and you will probably be able to see plenty of pin holes. I have heard that layering 3 copies together works. This may not be good enough for very fine detail work.

Source record: 108782

> I have a couple of Ramsey kits that run great on the battery, but when
>I try to hook them up to a power supply they don't work as well.

Several things come to mind:

1) Is the regulator you are using connected properly? (If you monitor the voltage on the output side of the regulator, are you seeing the voltage that you expect to see? Done assume! Check it with a voltmeter!

2) I am not familiar with the 7808. Is this a variable voltage regulator, or a fixed 8 volt device? If the latter, this may be your problem. Maybe your 9 volt equipment *needs* 9 volts!

3) Are you using the recommended filtering/decoupling capacitors? The app notes I have seen for the 7805, for example, usually feature a small electrolytic cap on the input side, and something on the order of .1uf on the output side (with respect to ground). If your equipment is analog in nature and more sensitive, you might need more extensive filtering. If you can, check the output with a scope.

4) Does your 12 volt supply have sufficient *current* capacity to power your equipment? What is the milliamp requirements of your equipment, and what is the milliamp capacity of your 12 volt supply? Obviously, the sum of the former values should be less that the latter value.

Hope that helps!

Hello, Folks:

Since I have had little, if any, luck getting an RS-232 cable for multiple nodes to work and even less luck with buying a commercial unit, I have decided to just do what I should have done to start with... Design one.

I am hoping that someone on the group can save me some time and point me to a site that has the IEEE spec for the RS-232 port. No sense in doing just another non-standard system that works some of the time... We have plenty of those already!

Thanks!

Can you run a transparancy through your laser printer? If not take the artwork down to a copy shop and they can do it. Coat your board with photo-resist and lay the transparance on top. Used to do it this way in the old (?) days.

This is probably the IF bandpass filter. Probably 70MHz
center frequency with a bandwidth of 25MHz (just a guess).

>2. IF transformer cans with "9050" on it

I believe JW Miller made IF cans with 9000 series part numbers.
I don't seem to have one of their catalogs.

>3. a six-legged (3 on each side) device from MiniCircuit Labs

: Good places to find schematics for FM projects?

: thanks in advance,
: -tony.

You can use the TDA7000 to begin building FM receivers up to 110MHz.
The TDA7000 is has internal mixer, VFO, FM descriminator (I think),
Which makes a good FM receiver. I don't have the schematics on-line,
but I can digitalize it if you couldn't find it. I think you will find
the scheme in the data book that contains the TDA7000 (if you don't
have one ask in your local store to see it), and you will only have to
add the audio amplifier.

PASSIVE SOLAR DESIGN USING COMPUTER GENERATED SUNCHARTS

The sunchart is an interesting and useful solar energy design tool. Basically it is a map of the sun's path across the sky during the year. It can be used as a basic solar energy design tool to aid solar designers in efficiently and easily designing and positionally optimizing solar collectors, solar electrical panels, passive solar homes, greenhouses, and other solar devices.

Optical Physics Technologies has placed an html article, "PASSIVE SOLAR DESIGN USING COMPUTER GENERATED SUNCHARTS," on the internet which provides information in using suncharts in passive solar design. It also provides a source of sunchart generating software and other solar energy design tools. This article can be found at:

http://www.srv.net/~tm_crw4d/sunchrt.html

For those without Netscape access, send me an e-mail message, and I will e-mail basically the same information to you. Unfortunately it won't have the same quality, but it should be useful. You can e-mail me at:

tm_crw4d@srv.net (note - my server is case sensitive)

As a last resort, I can also snail-mail a booklet with the same information, but I will need to recover my costs for postage, handling, and copying. If you want a hard copy snail-mailed, send $6.00 to cover postage, handling, and copying expenses. If you are outside the USA, send $7.00 in US currency. Send this request to:

From: dickv@cis.co.za
Message-ID: <4b7ach$a6j@africa.cis.co.za>
Source record: 108795
Cross-posted to: sci.electronics.design,rec.audio.tech,rec.radio.amateur.homebrew

The problem I have is a turntable with a magnetic cartridge (output around 2mv) and a mini stereo system which only has an AUX input (around 700mv) and I need to get the output from the turntable up to a suitable level to drive the system. I guess I will need RIAA compensation as well.
Can anyone help me with a suitable design, probably built around a single IC. I have 12V DC available in the turntable so power should not be a problem.

Thanks in advance

Dick Vogt (dickv@cis.co.za)

I wouldn't even bother trying to build something. Go to a large stereo
service company and tell them you need a junker. Then just rip out the
phono preamp/EQ circuitry.

6134. Audio Filters & AGC

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-19 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <819458675.1774@pinetree.microserve.com>
Source record: 108797

The HF transceiver I'm using employs audio-derived AGC and has an internal audio notch filter. I also use an external audio filter. The problem is that that both filters are in the signal path after the AGC detector. They do nothing to prevent a strong interfering station from activating the AGC and burying a weaker desired signal.

I'm thinking about modifying the circuit to place the detector after the internal filter, and to also allow injecting audio from my external filter at a point ahead of the AGC detector.

Assuming the external filter is unity gain, does anyone know a technical reason not to do this? Does anyone know if any commercial units are configured like this (Ten Tec maybe)? Alternately, I might simply add an outboard switch to turn off receive AGC altogether, but I don't think this would be entirely satisfactory. The desired signal isn't always weak, and AGC action is often needed even though the filters are in use.

Any suggestions or ideas on this problem will be appreciated.

73,
Jack WB3U

Poor regulation? Too much ripple? Maybe 8v not enough?
Try inserting two 1N4001 diodes in series in the ground
lead of the 7808 to raise it 1.4v higher, making it act
like a "7809.4" (hi hi). I've seen ckts that were kinda
picky about voltage, this may help.

I got to thinking after I posted my first response. Could also be common mode hum or something along those lines. Try adding bypass caps on all leads into and out of the equipment. if it seems like an RF problem, also use shielded cables in addition to the bypass caps.

> unwanted sideband cancellation.

Not only in theory but in reality, too. (See Campbell's Jan 1993 QST article.)
But in practice, "near-perfect" is problematic; you'll have trouble getting more
than about 40 dB of opposite sideband rejection from this approach. It's
interesting to note that the current crop of commercial amateur-grade
transceivers that use DSP do the demodulation at a low IF (up to 15 kHz or so).
By processing a single IF signal (not two signals in quadrature), they eliminate
any worries about amplitude and phase balance between two analog channels. While
such an approach is viable only in a superhet design, the complexity of the
needed superhet circuitry is not substantially more than that of a quadrature
D-C design.

6139. Low power FM transmitter ICs

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-19 00:00:00 UTC
From: David Skinner <david@drspc.demon.co.uk>
Message-ID: <565751427wnr@drspc.demon.co.uk>
Source record: 108802

Can anyone help me??

Do any of the major semiconductor manufacturers make an off-the-shelf IC which operates as a low power FM transmitter? You know, the sort of thing one might use to build a cordless baby alarm or bugging device.

Thanks in advance for any info!

(P.S. I already posted this question once but, for some unexplained reason, my news software changed "FM" into "FX" in both the subject line and in the post itself! I would put one such mistake down to a typo but *exactly the same mistake twice??* I don't think so! It'll be interesting to see if the same happens this time!)

FWIW (I'd hate to get flamed for being "an AOL newbie"...I have had .edu
and .compuserve addresses for some time) I just thought my computer had
locked up!!
Lost track of how many minutes (on a 14.4-dedicated line) and when
downloaded the (admittedly lame) default AOL viewer won't display.

6142. Where to find 2.5mm stereo phono plugs and jacks?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-19 00:00:00 UTC
From: pmbutter@wb.xerox.com
Message-ID: <NEWTNews.819386780.18117.Pbutterf@butter-pc.ess.mc.xerox.com>
Source record: 108805

I have struck out finding 2.5mm stereo phono plugs and jacks. You know the kind; they're used as mic connectors in HTs. Radio Shack doesn't have 'em. Nor does AES or DigiKey. Local industrial electronics suppliers don't have 'em either. Anyone know of a source of these? Or better yet, a source for the combo plug used with Icom HTs which has one stereo 2.5 mm and one mono mini phono plug adjacent for use with speaker mic. Application is homebrew voice "keyer" and also TNC interface.

I'm using my cnc machine right now. I wrote a program that converts hpgl
files and controlls the cnc machine. If anybody needs something like that,
I can give it to you. Maybe I'll make shareware out of it.....
It's slow but it works pretty nice.

6148. Re: RAMSEY kits - converting from battery - Problem.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-20 00:00:00 UTC
From: mikeheit@aol.com
Message-ID: <4b9dn3$f3c@newsbf02.news.aol.com>
Source record: 108625

I had problems with common-mode hum in a Ramsey receiver kit.
The unit would sound fine when powered from batteries but hum like
crazy when connected to a power supply.

Be sure your power supply is filtered properly, including bypass
capacitors on all leads to and from the kit. Use shielded cables,
too. All these things helped with my kit, but I didn't completely
eliminate the hum until I modified the power supply itself, adding
bypass and filter capacitors in various places.

Good tips for fixing common mode hum can be found in several
textbooks, including the QRP Notebook.

>Mind you! It's a guess, but I bet a 5:1 transformer would work O.K.

Careful here. Generally when speaking about impedance matching transformers, it is the impedance ratio that is specified. In this case, the turns ratio is given.

>Use a ferrite core intended for HF, 5 turns of small wire, (#20)
>wrapped around a single turn of #16.

Can't comment on the performance of this, however, matching this large a ratio is usually done in a couple of steps especially when reactive matching.

RS-232 was never intended to work with multiple nodes. If you
design something that *does*, you will have designed something that is
not compatable with RS-232.

RS-422 or RS-485 may be what you really want. I'm sure a little
searching will locate a .faq or three or twenty that will help.

From: jgrib@aol.com
Message-ID: <4b9rjj$kg2@newsbf02.news.aol.com>
Source record: 108630

Hi,

I did use a 20 meter MFJ from the car with a Hustler mobile whip on the rear quarter panel of the wagon. I worked a few stations in Fla, and one in the USSR. It does work, the only reason I don't do it all the time is the traffic here in Del. can be pretty nasty especially at rush hour. I received reasonable (ie. 559, 439 etc.) signal reports from it. I wouldn't want to run it say on 40 meters early in the afternoon due to the QRM from broadcast stations, but it's fun for a change from 2 meters FM.

Equalized preamp modules were a stock item 20-25 years ago. Just a
little metal box with a couple of RCA jacks for input and output, and
a power cord. Find an electronics/stereo store that's old enough to
have a decent back room. They were used to adapt record players that
used ceramic pickups for new turntables that used magnetic ones.

A quick search turned one up in the MCM catalog for $US 12.75. So also
check with distributors that specialize in repair parts.

6160. 222 MHz Tx designs ??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-20 00:00:00 UTC
From: hduff@humnet.humberc.on.ca
Message-ID: <8195012486505@lss.humnet.humberc.on.ca>
Source record: 108637

I'm thinking of building a transmitter for the FM portion of the
220 MHz band and using my scanner as a reciever just to try out
the local repeater activity. Wondering if anyone has any neat
designs ?
My initial approach is to borrow the 220 MHz RF strip from
"The Elevator" 222 MHz trasnverter article (Jan.90 QST) and running
a PLL/VCO synth into it. This design uses 2 MMICs, a 2N5179 and an
MRF227 for about 1 or 2 watts of 222 MHz RF.

Any comments/suggestions welcomed.

Thanks...

You may be able to make a serial-to-parallel converter. But, I guess you
might have good solution after you go through your printer manual. It
probably has a serial interface option or already have one.

> Dick Vogt (dickv@cis.co.za)

Dick,

There are external phono pre-amps available commercially. Radio Shack
(or whatever they are called in .za) used to sell them and most
electronics supply houses (MCM) will have them for around $15 US.

Almost any databook that deals with low noise op-amps will have a few
schematics for phono amps. Check out Burr-Brown, Analog Devices,
Linear Technology, Phillips/Signetics, and (of course) National. Keep
in mind that most of them will be for split supplies (+/- 15V). but
they are easily adaptable to single supply.

Take a look at Application Note 142 from Phillips at:

http://server1.pa.hodes.com/ps/philips5.html#5

Our LM381 and LM382 are optimized for single supply tape head and
phono amps. Most of the needed circuitry is built in, so less parts
are required (LM382=5 parts/ch). Take a look at these at:

http://www.natsemi.com

In LINEAR/AUDIO CIRCUITS find the LM381, LM382 and AN-299.

Unfortunately, AN-64 is not available on-line. It gives some very good
info on how to design an RIAA pre-amp. Contact support@tevm2.nsc.com
for it.

I used the LM382 years ago for a tape head amp. Be very careful about
layout. Because these circuits are relatively high gain, they have a

tendency to oscillate. One-point grounds, good shielding and power supply bypass caps are essential.

Also take a peek at:

Analog Devices http://www.analog.com
Burr-Brown http://burr-brown

Check out the 'low-noise' op-amp datasheets for any phono-amps.

Good Luck,

Hello,

First: Does anyone of you know Edward L. Meade, W1OX or Russ Miller, N7ART.
Do they have an email adress?

I am looking for their (our your?) help: They designed high-power-amps for
2m and 70cm. I got some russian tubes (GS35B and GIxxx) and want to know if
these are working in 3CX1500 or similar designes.

Second: Is there anyone who can give me a copy if W6PO's articles on 220MHz
144MHz amps published in Radio Handbook, 23rd ed. (Indianapolis: Howard W.
Sams and Co., 1987), pp. 18-2 through 18-7 and pp. 18-11 through 18-15?

Thanks a lot!

Yes indeed, Motorola makes an MC13175 and MC13176 that are
single chip crystal controlled xmitters. Just a crystal a couple
of resistors and caps, and a coil. They can operate AM or FM.
They will operate up to about 1GHZ. The 175 runs at 8 times the
crystal frequency, and the 176 runs at 32 times the crystal freq.
I think DC Electronics has them in the surface mount package.

6167. Simple QRP projects

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-20 00:00:00 UTC
From: kmiller@airmail.net
Message-ID: <4b7pr5$aav@news-f.iadfw.net>
Source record: 108815

Boy, I didn't know there was this much interest. Ever since I opened my mouth about a 40m transmitter built out of nand gates I've been inundated by requests for schematics! Sounds like we need to have a qrp net...

I don't have the schematics in electronic form, but I do have a few references to get you started looking them up. After Christmas I'll see what I can do about scanning them so I can e-mail them instead of using snail-mail.

First, there are several schematics, albeit ascii drawings, at this URL:
www.acs.ncsu.edu/HamRadio/HF/qrp/projects/

Here are a few fairly recent articles with simple projects:

August 1995 CQ, pg 71 - 250 mW tx with nand gate oscillator, a nand buffer, 4 "nands" in the final (!) and a nand gate to key it. Even simpler than my tx which has 2 - 2n2222's in the final!

Nov. 1994 QST, pg. 84 - Single chip tx using a 74HC240, claims 1/2 watt, probably a bit optimistic.

An older article for a single transistor rx is in the Oct. 1986 73, page 54. I have several others, but I left them at work to copy them. More to come when I find them. The bad news is that I still haven't located the original article I mentioned about the 40m and 80m transmitters. They were from 73 magazine, around 1990 or 1991. The 2 rigs were called something like "Ether duster" and "Cloud Buster" or something catchy like that. If anyone is familiar with this article, please post if for those who are interested. Judging by the amount of e-mail I've gotten, there must be more interest in QRP and simple construction projects than I thought!

I'll post the other references later, and will try to get the schematics scanned after Christmas.

73,
Kerry Miller

Ok, so now the whole internet world knows how disorganized my shack really is! I found the article about the 40m and 80m transmitters, called "ether duster" and "wave bender". I was close.

The article was in the May, 1991 73 Magazine, pages 26 through 29. Don't panic, most of it is advertising (way to go, Wayne...). The 80m version uses a color burst xtal and 4 - 2n 3904's in the the final. the 40m version has fewer parts and has a pair of 2n3904's. I used 2n2222's because I had a bag full and it didn't matter if I blew up a few!

More references to come, I'll try to scan some of this stuff in after Christmas.

6169. HF installation in Toyota pickup

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-20 00:00:00 UTC
From: zygo@azstarnet.com
Message-ID: <zygo-2012950753440001@usr7ip18.azstarnet.com>
Source record: 108817

I expect to take delivery of a new Toyota pickup soon and wonder if anyone has had experience installing an HF rig and antenna in one. I'd be interested to know of mechanical arrangements that have worked and especially whether any unusual receiving noise problems or car electronics problems were encountered. If so, any solutions. My tentative plan is to install a screwdriver or bugcatcher at the outer left rear of the bed. There will be a fiberglass shell, which hopefully will have little effect on the antenna. Thanks and 73.

>_____

Hi John:

I hope you don't take offense at this, no flame intended. My question is, why do want better resolution than the Century 21 offers. A number of years ago, I tought a radio class at the local Community Collage where the radio club had one of these rigs. If memory serves me (always a dubious proposition), the dial had at least 1-2 KHz accuracy, if not better.

If you avoid the band edge by this amount, why worry? Thousands of us entered ham radio with equipment no better than this, often worse, and everybody used to get by without a digital readout. I'm working weak-signal tropo, meteor scatter and EME without one.

By all means build things, it's a great part of ham radio. If you build a counter, fine, but don't do it because you are reluctant to operate without it.

Best wishes for a long and fulfilling ham experience.

>Assuming the external filter is unity gain, does anyone know a
>technical reason not to do this?

One reason to be careful is the fact that the AGC doesnt't react to
the total received signal strength within the IF passband. The filter
removes a significant portion of the signal, so AGC-action results in
higher gain and as a result the IF-amolifier or other amplifers more
up-front may get too much signal and operate non-linearly. This is
most likely in case you filter out a strong carrier or CW signal.

Does it help if I repeat the book...?

@ 30 Mhz. 50 Watts, input = 1.56 - j.89

So, my guess is @ 21 Mhz, you'd have 1.75 ohms and -j1.0 .

Mind you! It's a guess, but I bet a 5:1 transformer would work O.K.

Use a ferrite core intended for HF, 5 turns of small wire, (#20)
wrapped around a single turn of #16.

It's not optimized, but I've had great success anyway.

There used to be cheap phono preamps available for your application at
radio shack (ack) and other parts suppliers. Call around and see what
you can find. If there are no more, e-mail me and I'll find you
something. Why not canibalize and old stereo am;plifier from a swap
meet or garage sale? The phono preamps were often on dedicated PCB's.

An American electronics magazine (Radio Electronics) has had several
small amplifiers in recent editions. If you're interested, e-mail
me your address. I'll copy the articles and mail them to you. All
I ask in return is some stamps, or maybe a Rand note or two (I collect
stamps and paper money from around the world).

If you have access to the National Semiconductor 1994 Linear Applications Handbook, look at AN-346 for several example RIAA preamp circuits using the National LM833 op amp. The same circuits should work equally well with any good op amp. The LM833 is optimized for audio preamp applications, but you shouldn't have any trouble substituting.

6179. Cupric Cloride PCB Etching

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-21 00:00:00 UTC
From: rex_allers@3mail.3com.com
Message-ID: <3994@bridge2.NSD.3Com.COM>
Source record: 108642

Last week, someone asked about using Cupric Cloride solution to etch PC Boards. They mentioned an old article in Ham Radio. I lost the original message so I can't reply in that thread, but here's some info on a different description of the process...

I don't recall seeing the Ham Radio article, but I have a book that has a chapter on the subject. The book is "Electronic Prototype Construction" by Stephen Kasten, copyright 1983. The CuCl2 method sounds good, but I have never got around to trying it.
His formula is: solid CuCl2 200 g, Conc. HCl 100 g, Water to make 1000 ml. Etching reduces Cupric Cloride to Cuprous Cloride. By bubbling Oxygen (air) through the solution in the presence of HCl the Cuprous Cloride is turned back into Cupric Cloride for more etching. The solution starts as bright emerald green. As etching converts it to Cuprous Cloride, the color goes to murky olive-brown.
The author used a bubble etcher made from a cooler (plastic kind used for drinks and food). The solution was heated to make etching go faster. The bubbles agitate the solution during etching, then are kept going after etching until the color of solution is restored. The solution grows as time passes (kind of like sourdough) but must be kept up by adding water and HCl.
The book has several paragraphs on how to maintain the solution, but basically it comes down to specific gravity to determine how much water to add and titration of a sample with NaOH to determine hydrocloric acid level.
It all sounds very good, but like I said, I haven't tried it myself. The book was good on this subject, but I assume it is out of print now. Some of the rest of the book is a bit dated, but not a bad reference overall.

> D-C design.

Traditional phasing DC receivers are limited to about 40 dB of sideband rejection because it
is very difficult in hardware to obtain the amplitude and phase balance required to achieve total cancellation. On the other hand, if the local oscillator were supplied by the quadrature outputs of an NCO, and the audio phase shifting was done in software (DSP), then the only source of imbalance would be the differences between the two mixers, nes pas? Thereafter, every conceivable AGC, selectivity, and noise reduction feature would come almost "free" because they would all be software functions.

Well Paul I don't know about inexpensive. But good is Down East
Microwave with the No-Tune transverters. They come as assembled or partial
or complete kits. Also the parts can be obtained and then put together.

Several people I have asked around here have told me that is the way
to go and with the end of a lot of traveling for work now I am going to
order a 432 MHz transverter from them.

Good luck on your search and I hope this is of some help to you.

BTW. One can obtain the address for Down East Microwave from QST,
CQ or 73 magazines.

Besides the front-end overload problem, placing notch filters and such in the
agc feedback path could cause horrible transient response, ringing, etc.
Could possibly make it unstable. It could also slow down the agc response,
which is always a problem with audio agc anyway. An el cheapo way to design
comm receivers, in my opinion.

Course, if you like to experiment...

6184. 3 phase mains supply

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-21 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995Dec21.110622.58778@ucl.ac.uk>
Source record: 108647

This is not really connected with ham radio, but perhaps someone here will know the answer.

Are the electric companies compelled to provide a 3ph mains supply to a domestic installation if someone wants it? I have all 3 phases at home, which I assume was fitted since the house uses electric heating and so has a fairly large load. A colleague want to run a small lathe which has a 3ph supply. Although I've thought of ways at proving 3 phases from 1, by far the simplist solution is to have the electic company provide him with all three phases.

Has anyone requested 3 phases in a house? I guess power supply ripple would be less of a problem and so smooting caps could be smaller, so it could be useful for ham applications.

I assume you are talking about connecting multiple TNCs together using
some kind of diode arrays between the RS-232 ports.

Sorry to be sarcastic, but,
if the devices are truly RS-232C compatible, this should _not_ work.

The original RS-232C standard was about connecting the computer (DTE
Data Terminal Equipment) to the modem (DCE Data Communication Equipment).
The standard does not contain anything about connecting two computers
together (requires a "null-modem", two modems connected back to back,
which can be simplified to a few crossed lines) and the standard definitely
does not talk about multidrop (one master and many slaves) and even less
about LAN configurations (peer-to-peer).

The diode array systems I have seen requires that the TNCs violates
the RS-232C standard by inverting the RTS signal and through a couple of
diodes inhibit others from transmitting by feeding the signal to the
CTS inputs.

> I am hoping that someone on the group can save me some time and point
> me to a site that has the IEEE spec for the RS-232 port. No sense in
> doing just another non-standard system that works some of the time...
> We have plenty of those already!

Sorry, I did not find a direct reference for it, but be warned, that the
standard is quite complex and deals only with the DTE-DCE connection.

The best definition of "RS-232 compatible" equipment that I have heard,
is that the manufacturer, when the product is initially released,
does know a specific _reason_, why the device would _not_ work
with some unspecified device that is said to be RS-232 compatible.
This does not imply that the two devices will work together if the
compatibility would ever be tested :-)

I am a keen shortwave lintener. In my search for perfection I have decided to attempt to build a shortwave radio based on DIGITAL sampling techniques. I am looking for a design that can :

1. Sample a 0Mhz - 30Mhz signal, digitally filter and pick out desired program.

2. Any other high performance method.

I know this is asking a lot but that must be a "WHIZZ" kid out there that knows a design or some way of doing this! Oh additonally the design must be as economically restrained as possible.

My initial thoughts around the problem were to use a standard front end and mix the incoming singnal down to somthing more managable but this presented more problems!

Thanks! for any idears given!

Jack:

An *excellent* article on AGC systems was by Mark, KN5S, and
appeared in the October 1995 issue of QEX.

Mark's article will answer most of your concerns and give you
some insight into why your proposed approach is impractical.

If you need a copy, let me know.

6188. picking harmonics off of vfo inductor?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-21 00:00:00 UTC
From: lbraden@mail.utexas.edu
Message-ID: <4bbvo6$gs7@geraldo.cc.utexas.edu>
Source record: 108651

A question for the more experienced builders -

Is it possible to successfully pick off the 2, 3,or 5th harmonic
off a VFO inductor by placing a coil wound for the harmonic close
to the inductor, both wound on a form positioned vertically off the
groundplane and trimmed with small trimmer caps? Perhaps wrapping a
single link of insulated wire around both coils?

Or would the mutual inductance cause problems. What I am wondering if
it isn't possible to pick off 50 mhz energy from a 10 mhz 30m vfo coil.
Of course, there are other more standard and successful approaches to
frequency doubling and tripling, but I am curious whether anyone has
tried this?

Thanks

Larry Braden KC5CWG

Just relate my experience on a 4-foot diameter 5/8" Cu tubing loop I tried. I am able to resonate it on 40, 30, and 20 with a 250 pF 5kV air variable and loop feed. When originally built, I connected the variable C to the ends of the loop with the braid from a good grade of RG-8U. I was quite surprised to find this braid warmed enough at 100 watts that the flux left from the soldering operation smoked! I finally replaced the braid with three paralleled lengths of #10 AWG Cu wire. It only barely warms to the touch after 10 minutes of CW transmitting. Lots of current in spite of the voltage! Operating inside a stuccoed house on the ground floor, it is about 10 dB lower than the outdoor center-fed Zepp. Not bad for a small antenna INSIDE the house amoungst filing cabinets and metal shelving.

I would strongly recommend against attempting this project with no knowledge of the device you have chosen to use. Get a copy of the Motorola RF Manual which I believe ARRL offers for a nominal price. I could walk you through the procedure, but you need some background of the device characteristics. The Mot book also gives a number of good tutorials on various methods of matching from HF to uwave.

Hi Dave,

Braid is notoriously lossy at RF. It isn't suprising you noticed the heating in a high current application like the loop. Smooth conductors are much better than woven conductors, as your test shows. That's a good thing to keep reminding people of.

Look at the ground straps on antennas or stations with that experience in mind. If you tell others how crummy braid is for a RF connection some of them will think you're full of it, hi. Think about the articles recommending using coax braid for the whole antenna, or recommend using braided coax to make capacitors! And what about those bazooka antennas that use lossy braid for an element?

Hi all,

Does anyone perhaps know how to use/program the new ECP/EPP parallel ports that one see nowadays on PC parallel interface cards?

I understand that they support the older nybble-based printer standard, but in addition also support a full bidirectional interface, which of course will make them that much more attractive for interfacing to ham-radio projects.

Any information or pointers would be much appreciated.

Source record: 108666

Hi Dave OM,

Your experience with braid matches mine and many others: Braid is a
terrible RF conductor. I once used some of that "ultra flexible woven
copper rope" sold at various outlets for connections to my balanced-tank
antenna tuner for tuned-feeders and center fed dipole. The wire became
so hot at 400W out, that it melted the solder joints in the wire connections,
and the wire discolored/turned blue as you watched. Replacing it with
stranded #14 insulated automotive wire eliminated all noticeable heating under
identical conditions.
A loop about that size/material at 20 meters has a theoretical BEST
efficiency
of about -6 dB referenced to a dipole, with both antennas in the clear
completely. This is easily verified using equations in either edition
of Kraus's "Antennas" textbook. Once the loop is placed in a poor environment,
efficiency will fall dramatically, due to coupling losses to nearby objects.
You don't need to add very much loss resistance to the 10 MILLIohm radiation
resistance to reduce efficiency a lot!

Happy experimenting, and 73,
Don, W6JL

>>device.

Motorola makes a number of them, as a previous respondent mentioned.
I've done a fair amount of work with the MC2833, which is a
single-chip NBFM transmitter designed for the 49Mhz cordless phone
market. I've built several transmitters with that chip, which is
quite cheap and available from DC Electronics, in Scottsdale AZ, which
is where I buy most of my RF ICs. (Get their catalog if you don't
have it! Their phone is 602-945-7736. FAX 602-994-1707. Fine
folks!)

The MC2833 has an on-chip oscillator that works in the 12-20 Mhz
region, with a varactor modulator and audio preamp. Two uncommmitted
transistors on the die allow some frequency multiplication and
buffering. For 6M work I use a ~17Mhz crystal and triple to 6M.

If you use both transistors in the suggested fashion (there are
circuits in the specs that I followed fairly closely) you get between
5 and 10 mW output into 50 ohms. You can hear that a LONG way off
with a reasonable receiver.

Larry:

One would hope that the loaded Q of this circuit remains high. If this
is the case, then the harmonic content is necessarily low. If you
attempt to couple out a harmonic at this point, there will be little
available unless you use very tight coupling/loading which will lower
the Q, thereby increasing the harmonic level and lowering the stability.

You said it yourself, there are more standard and sucessful methods <g>.

> is very difficult in hardware to obtain the amplitude
>and phase balance (reformatted for clarity)

I've measured as much as 50 dB with an analog design. Don't know
how much it will drift over the next decade, though. I think phasing
can work much better than the filter method for a CW only receiver.

1) No problem with low pitched CW. With the filter method your
opposite sideband supression degrades as you lower the
pitch.
2) You can create a deep opposite sideband null at your
favorite pitch. Much harder to accomplish with
the filter technique.

DSP designsers should not assume that the mixers are matched,
particularly ones using little ferrite cores. Two mixers on
the same piece of silicon ought to do a lot better, but I don't
know of any high dynamic range ones available to amateurs.

Hey Gerald,

Lightning behaves more like RF than dc, so braiding *stinks* for lightning grounds.

Braiding is actually only good for very low frequency (power line or audio) or dc grounds.

Hello OMs,

recently I got some russian tubes GS35B (triode, Ua=3000V, Pa=1500W, fmax=1000MHz). It is large and heavy (2.8kg). Its datas seem to be comparable to the 3CX1500/8877 exept the maximum operating frequency.

Now I am looking for a design of an amp for it. I already have some suitable designs for 2m (K1AGB in QST 12/73, N7ART in QST 12/94 and OZ9ZI private copy). But as far as I know the 3CX1500 is not working on 70cm I never saw any design. Do you know a design? Maybe also another for 2m?

Also, I specially look for the articles references by N7ART: W.Orr, Editor, Radio Handbook, 23rd ed. (Indianapolis: Howard W. Sams and Co., 1987), pp 18-2 to 18-7 and pp 18-11 to 18-15. Anyone who could send me a copy?

Thanks a lot in advance and Merry Christmas and a Happy New Year!

Almost all the energy in the tuned circuit of an oscillator
is at the fundamental frequency. Probably less than a percent
at any harmonic. You could use a loop and a diode to produce the
harmonics or a non-linear amplifier.

6216. 3 phase mains supply

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-22 00:00:00 UTC
From: tkomljan@mobility.COM
Message-ID: <30DAE54E@msgate.mobility.com>
Source record: 108679

The European philosophy in using 3 phase is very different than North America. Many European countries offer 3 phase mains supply to households (especially farms) as a matter of course.

In North America, many non-industrial areas (residential and rural) only have single phase available. Why? Because the whole street is fed on the primary side with only one phase. Loads are balanced by alternating the streets and their respective phase. It would not be possible to obtain 3 phase power on such a street.

Now the big disadvantage, even if 3 phase is available: More expensive metering! Single phase customers under 50 kVA pay only for real power, as measured by a kW/Hr meter. Three phase customers also pay for "demand", that is, a penalty based on their highest load for the month. The biggest users also pay for power factor, either 90% of kVAR or kW/HR, which ever is greater. The minimum billed for a month is also higher for 3 phase customers.

While in Europe, finding a single phase motor larger than 1 HP is unusual, in North America, single phase motors to 7 HP can be obtained. These motors are usually much more expensive and larger than their 3 phase cousins, and require some capacitive power factor correction, due to their poor power factor. While PF is not charged at the meter, the lines supplying such a large motor will suffer much loss, if the current and PF are not improved.

Despite the initial high cost of a single phase motor, the more economical solution in North America for operation of a small lathe or table saw, is to go down to the motor rewinding shop, buy a single phase motor and convert the device it drives.

Cheers!

Tony K, VA3TK

Hi:
The answer to your question is "You can do it. For a price."
I'm not sure the power company can be compelled to do anything they
don't want to do, but dangle enough money in front of them and they
will oblige.

The problem is 2 fold. Some residential areas don't have all
three phases distributed. If your poles have three wires going
across, then there is three phase available. If the three phases are
available, they will probably only charge for the 2 extra transformers
(several kilobucks here) and for the power lines run to the house.
Then, of course, you have to have the house wired according to the NEC
and local codes. The local codes are probably more of a stumbling
block than anything.

I sincerely doubt that you have 3 phase to your residence,
unless someone went to a lot of trouble. Just having electric heat
does not indicate a need for 3 phase. What you probably have is 3
wires from the transformer. This is called sometimes 2 phase. What
it is really is a 240 volt center tapped single phase. Each 120V side
is 180 degrees out of phase with the other side of Neutral. You can
pull an incredible number of amps from a single phase 240V drop
depending on the transformer.

The cheapest thing for your buddy to do is to buy a new motor
for $200 to $300 and convert his lathe to a single phase 240V
connection. Of course, if he REALLY wants 3 phase, I will design and
build him a converter for about $1000.00 depending on load current!
They aren't that hard to do if you are driving a motor.

Oops! Stupid me.

I should read the "byline" before replying. I keep forgetting this is an international venue.

All of my responses were applicable only in the USA. It turns out that power distribution is one of the MOST nationalistic areas still left in the world other than telecom. Hopefully, someone in the UK can give you an appropriate local answer.

Most of my ideas probably still hold. The cheapest approach is still to just change the motor with a single phase motor.

Hi,
The cheapest way to 3 phase power from a single phase line is to
build yourself an idler motor. Here's how you do it. Get yourself a
3 phase "Y" motor that is twice the horsepower of the largest motor you
want to start. Go to your refrigeration supplier and get a "super starter"
that will handle a 5 ton A/C unit. A super starter is a positive temp
coef. thermistor that is very low resistance when cold, and high when hot.
And find yourself an oil motor run capacitor of about 25-50uf per HP of your
idler motor. It must be AC rated for at least 330VAC!

I call the phases of your idler motor A,B, and C, and the power line L1, L2.
I call the phases of the load A,B, and C.

```
240VAC L1----BREAKER-------------------------IDLER-A---MAG-SWITCH--LOAD-A

240VAC L2----BREAKER--+----------------------IDLER-B---MAG-SWITCH--LOAD-B
|
+-SUPERSTARTER--CAP---+--IDLER-C---MAG-SWITCH--LOAD-C
| |
+---RUN-CAP-----------+
```

The "RUN-CAP" is optional, but will help with power factor correction and
balance of the phases. The only suggestion I can give for run cap is it
must be oil, and around 5-10uf/HP. To get to the correct value, you
measure the current in all three phases of the load motor, and adjust the
run cap for best current balance.

The "MAG-SWITCH" is usually called a magnetic starter control box. It is
basically a latching on off switch that will default to off if primary power
is lost momentarily. It should already be part of the machine you are trying
to power. You can use a "Knife switch", but make sure the load is
turned off before switching on the power to the idler motor.

The "SUPERSTARTER" should only cost $20 or so. If you can't find one, you
can replace it with a high current momentary switch. Turn it on until the
motor starts, and then turn it off. Note, if power fails, you will blow your
breakers when it comes back on! Also note, that the superstarter takes a few
seconds to cool off and reset itself, so you might lose a breaker if power
fails for a short period of time. I find that if there is any rotation of
the idler's shaft, the run capacitor will start it back up, so this isn't a
biggie.

This is the basis of the rotary phase converters made by companies like
RONK, and moliphase and cost $1000. You can build yours for under $100.

Brent, you shouldn't cross off the 8877 because of expense. They are beginning to turn up with great frequency on the surplus market, often out of medical imaging amplifiers. I picked up my last one for $160, which compares favorably with a pair of 3-500Z's.

Brent,
I hate to sound like a broken record, but I think there is an amp schematic in the handbook for a pr of 3-500z's. There is also one for 8877. You should be able to get a used 8877 if you shop carefully. Both amps are a little over-designed with features, IMHO. If you build one with 8877's or any other ceramic tube, you need to be sure to include any grid current limiters or grid trips, fuses, etc. Excessive drive/grid current will wipe out a ceramic tube in a hurry. I am using (however infrequently) a pr of 3-500's. They sure light up pretty, lets see you do that with an 8877!
Alpha used 8874's for a long time, you might find some of them second hand too. If you buy them second hand, make sure you can get your money back or get the guy to demonstrate them in his amp. You can't tell my looking if they are good or not. At least a glass tube you can tell if the plate has holes blown in it!
Have fun building the amp. If you have old tubes lying around, I think I also have plans (somewhere) for a pr of 813's and one for 2 or 3 - 811's. This is a big switch from the qrp schematic thread I was in!
73,
Kerry

Lets not forget the old old trick of making a rotary transformer by exciting one phase of a three phase motor with a flywheel attached! If you can find an old three phase motor inexpensively of about the same rating as the one in the lathe, then one simply applies single phase power, kick start the flywheeled "transformer" and apply the three phase connection to the lathe motor. Do pay attention to the current rating of both when you do this. You can start and stop the lathe without turning off the "transformer" as well! Cliff Buttschardt W6HDO

You can definitely feed it through your 4L. I have done it on mine
without any problem. The process the printer uses is essentially the
same as that of a plain paper copier.

The problem is that I couldn't get a good transfer from the film onto
the PCB.

The MRF454 is supposed to be some kind of a replacement to the MRF450.

MRF454 has (at 12.5 V, 60 W out, 30 MHz) the following input
and output impedances:

Zin = 1.66 - j0.844 ohms
Zout = 1.73 - j0.188 ohms

Have a 1992 toyota P? with an aluminum cap. have run my yaesu FT-757GX with a tuner in it with no problems whatsoever. When I bought it, I asked if it has computer chips, electronic controls, etc... the dealer said no. I said "good- I'll take it!" (this was in the U.S, BTW). Works FB- no noise that the factory supplied Yaesu NB couldn't take care of on any band. Keep leads to ground really short and U should be fine.

My truck is a 2 wheel drive STRIPPED base model, not 4WD, not the T-1000 or Tacoma, BTW.

I have abused the living shit out of this truck- missed oil changes, high miles (100,000 since march 1992), put in and take out a military radio shelter (I had to add $245 worth of rubber spring savers- REALLY WORTH WHILE INVESTMENT if U are going to be using it HARD. Mine worked fine for 2 1/2 years w/o them, but needed to add them when I got the radio shelter. Have filled it to the brim with books, wood, moved 3 times, etc, etc.- has never let me down. Not bad for a $7,800 investment New.

Again, NO RF PROBLEMS AT ALL. Good luck!

The DSP approach I'm thinking about would use hardware for the mixers, post mixer lowpass filters (needed to keep out of band sigs from overloading the DSP), and pre-DSP audio amplifiers. The phasing, variable bandwidth filtering, and AGC would be done in software. The DSP processor could also control an input attenuator for compound AGC.
Of course, there would be considerable potential for differential amplitude and phase between the two DSP input channels, but an adaptive equalizer could be programmed which determines these errors by tuning across a reference carrier and building an equalization table. The resulting receiver would be high performance, feature rich, extremely reproducable, and easy to adapt for multi-band operation.

I would use a 300 ohm to 75 ohm transformer at the center of the
antenna (the type sold for use with 300 ohm TV antennas at Radio
Shack). They cost less than $3.00 and the mismatch between the
90 ohm coax and the 75 ohm input to the transformer will be
insignificant in terms of receive efficiency.

>any design. Do you know a design? Maybe also another for 2m?

The max freq rating for the 8877 is 250 MHz, so this probably explains the
lack of articles for 432. The 8938 is essentially the same tube with
a coaxial base and is rated to 500 MHz. I believe there is a published
design using the 8938 on 432, but I don't have it at hand.

I don't have this edition, but perhaps it is the same as in the 22nd edition.
If this is the case, the design was first published in "ham radio magazine",
August 1971 and reprinted as an EIMAC note AS-47. I am using this amp on
two meters and it performs flawlessly. I highly recommend it. If this sounds
interesting, email your address and I will forward a copy.

>Ham manufacturers do radio DSP by using a very very low IF. So low it's
>almost at audio. So it's almost exactly like audio DSP anyway!!!!

This brings an interesting point. How far should one go in hacking an old rig? Personally, I own the rig not because of its resale value. I don't figure on ever selling it. Yes, I am a major packrat. I figure that if I ever get rid of it, it will because I have toasted the rig so badly that I can't even salvage parts. At that point, I'll buy another one and start all over.

The high price of DSP chips is a case in point. In order to add it, I will be spending MORE on the enhancement than the actual worth of the rig. Does it bother me all that much? Not really. I figure that I run a higher risk of toasting the DSP chip while experimenting than actually enhancing the rig's performance. But what the heck! I consider it a pretty neat hack and worth while doing all by itself. The trick however, is to choose a project that is sufficiently difficult that you end up learning something useful but not so difficult that you give it all up entirely.

As someone who is building single units and not mass producing anything, cost effective manufacturing is not a factor. I can try things that any sane manufacturer would never try if they are interested in staying in business. I don't have to worry about the marketability and pricing of the unit. Profitability is not an issue. My benefit from playing with the rig is the hack itself.

Personally, I think more hams should try picking up a soldering iron. So what if you get burned once in awhile from the soldering iron because you are extra clumsy or if you decide to build something that toasts your equipment? The aim of the game is to try to do something that you could do before or thought that you can never do. Who knows, you might surprise yourself! But then, to each his own. Different folks for different strokes.

P.S. A great starter project for those who are inclined is the CMOS Super Keyer. While I haven't personally seen version III, version II is very easy to build. From the article in QST in August, none of the changes made in version III would make it

any harder to build. You end up with a useful unit with only an afternoon's work. There is nothing so tight that it is difficult to solder. The problem with the keyer is that once you build the kit, you might actually become tempted to become proficient at CW.

Try it, Mikey, you might like it.

Another problem with the kit is that source code is not available for version III but that is another thread entirely :) Does anyone have the code to version II lying around? I have been meaning to ask for it.

^^^^^^^^^^^^^^^^???
>picture of schematic to see clearly and install a jumper froM IC32 pin
>11 to the point where you cut the trace. This will restore transmit
>from 135 to 175 MHZ.

I was looking at the information given in this mod and comparing it to the schematic. This mod seems to be legit. The jumper labeled W4 on
the schematic appears to be the green 0 ohm resistor just to the rear of D59. In the USA version removing D60 and removing W4 would be the
same thing.
I believe that removing D60 just prevents the radio from tx on aircraft band after the VHF mod is performed. Removing Q38 or R353 would have
the same effect as cutting the yellow wire (J4). The receiver would work better if the yellow wire is rerouted to the VCO switching
transistor. So all that is left is pin 11 of IC32. This pin is the same as the orange wire next to the famous yellow wire. All this wire
does is supply 5 Volts whenever the radio is outside the 0-60MHz range. This wire labeled L8 on the schematic is the one responsible for
enableing the 2 meter bandpass filters that are located in the PA unit. It also disables the high power amplifier which consists of a pair
of MRF 255 and is used in the HF and 6 meter bands. It appears to me that all that is preventing the radio from txing outside the 144-148
range is a control pin. The PA unit appears to be fully enabled in the range 118-174. The control pin that disables the out of band TX must
be acting on one of the pre driver stages maybe IC1 or IC38. Now if we could find this missing information about the control pin, all that
would be necessary would be to rewire it to the orange wire. This would enable it in all the range 118-174 MHz.

On the receive side, it appears like the 60MHzHP/129MHzLP filter that is selected for receive anywhere outside the ham 2 meter band used to
be a (60-200) filter. This would explain why this filter would have been selected the way it is in the unmodified version.

Now that I got a copy of the schematic I am making a list of things that I'm going to change to the radio. I just wished that Icom would
have engineered the radio a little better. Although the radio is an outstanding attempt at

a tribander all-mode radio, it could have been a lot better.

>groundplane and trimmed with small trimmer caps? Perhaps wrapping a
>single link of insulated wire around both coils?

Here's what I've successfully done to get a 975 MHz harmonic from a 325 MHz VCO -
1. Design the VCO with tank circuit/feedback in the base-emitter.
2. Take the desired fundamental from the tank circuit.
3. Use the collector to drive a 50 ohm load. This low impedance will help minimize interaction between the collector and tank. The collector waveform will be very rich in harmonics because it's produced by the highly non-linear collector current waveform. A spectrum analyzer showed the 975 MHz at a few dB below the fundamental.
4. Filter the collector output as required to subdue the undesired spectral lines.

Hi!

A couple of Italian Hams have designed a PC board for reception of HRPT weather satellite data. I bought the board from them but I have to buy all the components. The one I can't find anywhere is this variable cap diode BB 505.

I've looked all over and have had some friends check around, none can find a cross reference. My hope is that someone here might be able to find the cross reference or a source.

As to my Italian Ham friends, they're off on vacation for a couple more weeks and are not available, I hope to have this prototype built and running before I have to return to work after the Holidays.

Thanks in advance and Happy Holidays!

I've found several BBxxx devices in a couple of catalogues, including a
BB405, but not the 505. They are made by Philips, apparently, which
might help.

I am actually looking for a commercially made gps time and frequency
standard to distribute around the company I work for to keep counters
generators etc. on a common standard.

I only suggested using video network feeds because there are many
Ham type frequency counters etc. that use 3.58MHz crystals as the
time base. I see video genlock boxes which will lock an oscillator
to a color burst from an external source running for about $10 at
fleamarkets. It is a far more cost effective approach for a hobby
bench than a GPS system.

Yes. Motorola makes the MC2833 FM transmitter chip. It is
usually operated with a XTAL at 1/3 the operating frequency and
requires a bunch of caps, resistors, and inductors to make it
work.

S>From Steve Drury. Email steve@hamlab.demon.co.uk

Greetings Steve:

I have written assembly code for the PIC 16C84 and have been
using a computer controlled DDS in some HF applications for a few years.
I would like to scale my DDS up to VHF using a modern PLL chip. I just
received a couple of PLLs from National that I would like to try.

I am very interested in your design and have the following
questions:

1) Please give a description of your VCO, low pass filter and
availability of parts and cost.

2) What is the frequency range?

3) What is the step resolution?

4) How fast does it lock up between steps?

5) Does it use a pre-scaler and what is the reference
frequency?

6) Would you e-mail your PIC source code to me so I could study
it?

7) Are you using a keypad and lcd display?

8) Which PIC are you utilizing?

Title pretty much says it all. Need a schematic for a DTMF decoder using the SSI202P chip (I picked up three of the chips at a swap meet for a buck each, they were still sealed in their Rat Shack packaging).

I need a unit that is handheld, uses an LCD screen, and is not connected to a computer.

Thanks!!

My version of Paul's question would be (and I always wondered why this wasn't answered long ago) what would be the preferred configuration (as in a plug and play solution) for running vhf/uhf fm, ssb, am/cw using, for example, my Ranger 2950 10-meter transceiver? There are so many of these out there, someone must have an auto-sensing, auto-switching add-on transverter that goes beyond the "get in the rig and cut it apart" stage. I think I saw an ad for a TOKYO 2-meter transverter a couple of years ago that claimed this kind of capability. Anyone know of such a "module" that does it all?

>> turn on the big amp.

That is always a worry when using a device not specified for a certain
service such as VHF pwr fets for low-noise 6 and 2 M preamps, using
internally matched devices for frequencies well away from the design frequency.

The May 95 RF Design article I referred to also has a class D amp with a
complex front end getting 250 w output from 10 mw input rated from 1.8 to
13.56 MHz. Of course this is not class C.

Richardson sent along a data sheet with detailed specs at 13.56 including an
amp using four devices putting 1000 watts out at 20 watts drive. The 1 MHz
capacitances are Ciss 1500 pf, Coss 90 pf at Vdd 300v. Nothing here
exciting except the big cap at the gates.

Thanks for the caveat, but have already received four of the devices (at $64
ea!, still less than replacements for the Dentron MLA-2500..which I've never
lost). Am in the process of adding copper heat spreaders to a foot long
piece of 3456 waveguide which will serve as a water cooled heat sink....have
left room for another set of devices if all goes well with this model. Also
am going to do away with all of that ferrite stuff and put a regular tube
type tank on the output. Since I have plenty of drive from the home-brew tx,
will do some passive drive to the gates with some attenuation to help the
driver (one of the Communications Concepts Motorola 140 w amps that has been
in service for 20 years and that someone has already suggested to the
starter of this thread...works well).

A first look a the pwr supply indicates that I'll need about 6000 ufd in the
filter and a good, low R-on bridge with a gradual charge circuit for

turn-on. From Allied, can get the C for about $100 so should have less than $500 in the amp if it works.

Of course, the question is why? The amp will be in a shed about 300 ft from the shack at the base of a vertical. I have other amps, but only work VHF and 160 CW so why put something more complex out there?

Will let you know what happens. Suprisingly, my worries are not of wasting money and time, but of the electrolytics. I heard in a round-about manner of a major company having one fail in a tight box, blowing the lid off, breaking an arm, and with the lid ending up stuck in a wall several offices away. I was present when a 40 mfd cap @ 4500 v blew opening up a rack and it easily awoke a bunch of tired contesters. This amp will have about 10 times that much energy stored.

Andy is absolutely right here. I have done this many times and the collector current waveform invariably looks like an impulse train. A standard technique is to put a parallel tuned circuit in the collector tuned to the desired harmonic. Works very well.

Source record: 108581

I got the interesting suggestion that a DSP
delay line be used to allow the DSP time to
do its signal processing. Supposedly, this
would allow the DSP to control the AGC.

This doesn't quite work, unless you didn't
really need the AGC in the first place. If
you do need it, those samples in the delay
line are worthless.

However, you ought to be able to use DSP to
combine multiple bit steams seamlessly. Suppose
you had four 16 bit A/D converters with different
amounts of gain ahead of them. Properly done, this
ought to extend the single tone dynamic range of
the system considerably.

6269. SB-220 Problems/Mods

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-26 00:00:00 UTC
From: n1mm@aol.com
Message-ID: <4bpcv3$bhg@newsbf02.news.aol.com>
Source record: 108582

I'm having trouble with my SB-221. Once in a while on 10 meters, more frequently if the CW/Tune - SSB switch is set to SSB, I get a loud pop. When that happens, the .82 ohm resistor in the HV meter circuit blows and I have to replace it. One time the meter went with it. It seems to be much worse since I changed the amp over from a 15A, 115v line to a 20A, 220v line. I presume because the "under-load" plate voltage is quite a bit higher now.

I have heard that this problem is either VHF parasitics, or dirty capacitors. Has anyone in this group solved this problem? Is there a FAQ on this?

Also, what is the general concensus on directly grounding the SB-221's grids?

Any help would be greatly apprciated.

Thanks.

I don't think so. The problem with hardware closed loop AGC is that it's a feedback system. It has processing delay, overshoot, undershoot, and all the other problems any closed loop system is prone to.
In the DSP approach, the audio samples could be 'buffered' in a delay memory. The processor would then analyze this moving sample, and decide when to apply the mathematical gain reduction in the FORWARD direction. The onset and amount of gain reduction could be perfectly matched to the requirement because you'd know what has to be done before the audio ever gets to the speaker. Kind of like knowing the future, and altering its outcome. Of course, it only works to the extent that there is reserve 'headroom' between the desired audio signal level and the overload point of the DSP.

Another suggestion is to use another stage at the output of the VCO
simply to do the frequency multiplication. In this case, I have always
set up the impedances so that there is a short to ground at the output
frequency at the input, and a short at the input frequency at the
output. This is supposed to make the conversion effeciency higher, and
so get the output at a higher level. Look out for stability and drive
level though. I battled that for 5 months on the last program I was
on. Of course, I was doing a quadrupler in a single stage at 1 Volt
Bias voltage, and I also has only about 1 mA to spend to do it. It's
working now, though.

What you describe is a VHF parasitic. Send a SASE to Rich Measures, AG6K,
at 6455 La Cumbre Road, Somis, CA 93066 or call him at (805) 386-3734.

Rich wrote several articles for QST describing the parasitic problem,
particularly in SB-200/221 amplifiers. He sells very inexpensive (about
$15) parasitic suppressor kits for most amps. Get his article reprints also,
and buy the other SB-220 mods such as the meter protection diodes, and the
lower heat bleeder resistors.

Good luck with this excellent amplifier.

But that's what dynamic range is all about. The above setup
is exactly equivalent to one 16 Bit ADC plus 3 attenuators/AGC.

Andy Borsa (andy@moose.mv.com) wrote:

: Here's what I've successfully done to get a 975 MHz harmonic from a 325 MHz
: VCO -
: 1. Design the VCO with tank circuit/feedback in the base-emitter.
: 2. Take the desired fundamental from the tank circuit.
: 3. Use the collector to drive a 50 ohm load. This low impedance will help
: minimize interaction between the collector and tank. The collector waveform
: will be very rich in harmonics because it's produced by the highly non-linear
: collector current waveform. A spectrum analyzer showed the 975 MHz at a few
: dB below the fundamental.
: 4. Filter the collector output as required to subdue the undesired spectral
: lines.

I think Andy's advice is sound. An example I saw was in the LO chain in a
450MHz pager receiver: 6V supply. 49MHz 3rd overtone xtal; tuned b-e
circuit. Tank in collector tuned to 3rd harmonic, 150MHz. DC comes down
through another transistor, which has its base driven by that 3rd harmonic,
and has a tank in its collector tuned to 450Mhz. Compact, and efficient use
of limited available power.

6285. Atlas 210X power output Question

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-27 00:00:00 UTC
From: "Michael G. Reiney" <mreiney@hevanet.com>
Message-ID: <4bsigj$o4j@vista.hevanet.com>
Source record: 108596
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I have an Atlas 210X that works fine on 40 meters and up. On 75 meters, I can only get about 40W out of it.
I hypothesize that if the high freq power out is ok, the transistors are good.
The 80M filters are not tunable, so they've probably not been tweeked.
Ideas?

The only thing I can think of is that one of the broadband transformers in the final have a cracked core and insufficient inductance to get to 80M. They look ok. I don't have any idea how to check it out without disassembling the transformer and checking each core. High risk of breaking something.

Any guidance would be appreciated. I do have access to equipment, GHz scope, spectrum analyzer etc. Don't be shy with wild test ideas.

thanks, miker

6288. Amateur-band distance measurement (radar, etc.)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-27 00:00:00 UTC
From: stevebragg@aol.com
Message-ID: <4bqslt$qke@newsbf02.news.aol.com>
Source record: 108599

I am a radio amateur experimenting with distance/velocity/acceleration measurement using a digital-code transit-time method. I have had some limited success, using a direct-FSK system with 223 MHz uplink and 1300 MHz downlink. If you're interested, the SPECS are below. If not, see the
PLEA below.

SPECS:
ANTENNAS: 6-el YAGI for the 223 Mhz uplink, and a 23-turn HELICAL for the 1300 MHz downlink. 1/4 wave vertical on transponder downlink, loop antenna on uplink.
GROUND RX: .95 dB noise figure. Downconvert to 28 MHz; use FM receiver (Ramsey) to decode FSK.
MEAS SCHEME: Used a simple PN code to lock the air-to-ground loop, and measure the 2-way transit time. A microcontroller averages and filters the distance data, and differentiates it to get velocity and acceleration.

TRANSPONDER: Linear transverter; does not demodulate data, only preselects,
amplifies, filters, and upconverts to 1300 MHz. Transponder output @ 1300 Mhz: 17 dBm. Sensitivity @223 MHz for 20 dB quieting: 0.2 uV.
Tap-off for
command receiver (remote control) @ 10.7 MHz IF.
USE/RANGE: Tracking amateur rockets. Range: 50,000+ ft. Up to Mach 2.
SHORTCOMINGS: Fading. Loss of loop lock on air/gnd loop. Acquisition. Too little power on downlink path. No auto-tracking ability. Measures in one
axis only (RX ant axis).

PLEA:
I am interested in hearing from EXPERIENCED
experimenters doing measurement work with HAM-BAND equipment.
Specifically, I would like to know:

1. What was the range of your system ?
2. What object were you tracking (rocket, ballon, plane, glider, etc.)
3. What was your modulation method ?
4. What characteristic of the signal did you use for measurement (transit time, Doppler, etc.) ?
5. What bands did you use ?
6. What power levels and antennas ?
7. Did you use a transponder, or a reflective/passive system ?
8. Does your system track the source? How (monopulse, conical scan, etc.) ?

... and anything else you think I should know. E-Mail me if you want more details about my system. I think hams should share successes (and failures!)

>I'm having trouble with my SB-221. Once in a while on 10 meters, more
>frequently if the CW/Tune - SSB switch is set to SSB, I get a loud pop.

You could be loosing the tubes, or another component. Sometimes the RF chokes arc through to the mounting screw, but usually its the tubes.

>When that happens, the .82 ohm resistor in the HV meter circuit blows and
>I have to replace it. One time the meter went with it.

Put a diode protection circuit from the negative end of the electrolytics to the chassis. The cathode of the diode (band end) goes towards the electrolytics. Use two diodes in series and bypass them with a .1 uf 50 volt disc cap. It also doesn't hurt to add a 20 ohms 25 watt HIGH VOLTAGE type resistor in series with the positive supply lead. The SB220-221 RF choke has very low surge limiting resistance.

>much worse since I changed the amp over from a 15A, 115v line to a 20A,
>220v line. I presume because the "under-load" plate voltage is quite a
>bit higher now.

The problem is likely peak voltage related.

>I have heard that this problem is either VHF parasitics, or dirty
>capacitors. Has anyone in this group solved this problem? Is there a
FAQ
>on this?

The parasitics thing is sort of a "fairy tale", the capacitor thing is sometimes true, but the tubes are the most likely cause.

>Also, what is the general concensus on directly grounding the SB-221's
>grids?

That should be done if you can do it. That circuit was a design mistake. It adds unwanted feedback and decreases the performance of the amp. By all means, ground each grid pin directly to the chassis by drilling a hole near EVERY grid pin and adding a lug. Remove the tubes first!

But the tubes may just be "gassing up". If so, they will arc once in a while when plate voltage peaks are reached. Ten meters has the highest Q and most touchy tuning, so it's more likely the PA peak anode voltages reaches a few times the dc supply voltage there. When that happens, if the tubes or some other component is "on the edge" and the peak voltage goes past the safe point.....pop!

By the way, if the tubes are metal anode types, do you get the tubes red once in a while to de-gas them?

>
>The problem is that I couldn't get a good transfer from the film onto
>the PCB.
>

I tried using the TEC-200 on a Laserjet 4 plus. It ran through the printer fine, but the traces left on the film had drop outs in the center of the wider traces. I had no problems getting the trace to stick to the copper board as long as the PC board was CLEAN. More on that latter. The drop outs were the same as I see on clear transparency film that is designed for a copier but used on a laserjet printer, or vice versa. With that in mind, I tried using transparency film DESIGNED FOR LASERJETS. Just the regular stuff you get at the office supply store used to make overheads. I got much better results as far as printing from the printer, but would it stick to the board? I was concerned that it may be stuck to the film so well that it would not pull off. To my surprise it did pull off and stick to the copper. I was making a very small board (1" x 1.5"). I don't know if I would have had the same results on a large board. By the way, in both cases I set the print density to HIGH via the control panel on the printer. This gave the darkest image.

The key here is a clean pc board and proper heat. I cleaned the boards used in this test by dipping them into my etchant solution (Ferric Chloride) for about 20 seconds. This gave them a pink appearence. Clean off any residue that remains. My heat source was an iron.

If you are going to do a lot of boards this way, DynaArt makes a heater that the PC board will pass through to give proper heat and pressure.

The print, iron and peel process does work, but you will need to experiment with various films, print density, board cleaning techniques, heat, and

pressure.

I still like the photo process for larger, more complicated boards. I use pre-coated boards from PCB Kits in Michigan. They are coated with positive acting resist. I use the laserjet to make the positive artwork. Expose it to a photoflood in a white box, develope and etch.

I didn't realize there was any "headroom"--a lot of people seem
to want more dynamic range than is available from A/D chips.

>> However, you ought to be able to use DSP to

One bit stream handles -140 to -60 dBm
another bit stream handles -120 to -40 dBm
another handles -100 to -20 dBm
the last handles -80 to 0 dBm
You can switch to less sensitive bit streams as the signals get
louder.

Thus, the system ought to handle signals from -140 dBm through
0 dBm without overloading. Of course, loud signals will prevent
you from hearing weaker signals simultaneously.

BTW, this probably isn't the best way to do it, but ought to
convey the idea.--Zack KH6CP/1

I've got the Analog Devices EZ-KIT Lite, which sells for 65 UK Pounds.
It uses the ADSP-2181, which is compatible with the ADSP-2115 used on
the PSA sound cards, for which there is a lot of amateur software
around; it won't be long before this software has been ported to the
EZ-KIT. It's not really a kit, as it comes as an assembled board,
together with development software. It interfaces to a PC serial port.

Xtal ladder filters are quite easy to design and build. W1FB's Design
Notebook (ARRL) has lots of info.

Zack Lau (zlau@arrl.org) wrote:
: >
: One bit stream handles -140 to -60 dBm
: another bit stream handles -120 to -40 dBm
: another handles -100 to -20 dBm
: the last handles -80 to 0 dBm
: You can switch to less sensitive bit streams as the signals get
: louder.

Except for a very small advantage in the ability to switch quickly
and with minimum transient, this should be no different than
switching gain ahead of the ADC. Unless you have money to toss at
ADCs, it seems like the switched gain (or just controlled gain) would
be a more reasonable way in the typical ham application to do it.

: Thus, the system ought to handle signals from -140 dBm through
: 0 dBm without overloading. Of course, loud signals will prevent
: you from hearing weaker signals simultaneously.

Another way to get almost all of that is start with something like
the Burr-Brown 20 bit delta-sigma converter, assuming we are talking
about baseband converters to go with direct conversion front ends.
Then you don't have to worry about switching anything. That system
has something around 90dB of dynamic range: that is, if you put in
a full-scale signal, distortion products appear at about the -90dB
level, but if you drop the input level, the distortion products go
down. However, noise starts to get you at the 120dB below full scale
level, depending on how you are looking at it.

These 20-bit (stereo) converters aren't exactly dirt cheap yet, but
it does seem like they are in striking range of hobbiests. Better plan
to do better than 16 bit arithmetic with the results, though! And to get
this sort of dynamic range, you must be very careful in your construction
techniques, and provide very clean power.

AC Power Supplys have a very low impedance compared to batterys.
Put a 22 ohm resistor in series with the power lead. This is
especially true if using the LM286 audio chip.

Newark has many pages of heat sinks. Last I heard they had a $25
minimum order. Their number (at least for a catalog) is 800-298-3133.

You might also try the Hosfelt, MP Jones and All Electronics catalogs.
If you need phone numbers I can look them up for you.

W8JI Tom wrote:

snip:

> By the way, if the tubes are metal anode types, do you get the tubes red
> once in a while to de-gas them?

What happens here to the gasses? Do they change chemically and become attached to something? Something like the getter? How did that work? Wasn't it Magnesium or some such which was vaporized inside the tube and chemically or mechanically bonded or absorbed the gas and stuck somewhere? If the plates are made hot, then this would work against the getter residue, so they must not use getters in transmitting tubes? But, the plates would absorb gases if they are made out of Tantalum (and what other materials?) and became very hot. I read that (Terman) Zirconium will absorb Hydrogen up to 350C but will give it back above that. Then if you have Zirconium also at 1400C it will greatly absorb other gasses. They can put two Zirconium filaments in at these two temps to clean up continuously. What does Eimac make.....say the 3-500 plates out of and if there are hydrogen and other gasses inside the tube over time then what is the analysis if you raise the tube plate to cherry red. All hydrogen? Is that better or worse than never going above 350C? Is that impossible in a transmitting tube? How hot is just below any color change? I suppose Eimac has studied this?

Sorry....just triggered my interest, cause it sounded like a well known fact that I am ignorant of.

This is seriously cool. If I recall correctly (and I'm at work and have none of my catalogs handy) Antique Electronics Supply here in the Phoenix area (Tempe, Arizona, actually) now sells a simple AM radio kit that uses subminiature tubes. They seemed to indicate that they made the kit up because of an *overstock* of submini tubes, so they're a good supplier option if you ever need one for this kind of research.

It's good to recall that the AA5 as we knew it in the late 50's was the product of over 35 years of product evolution and relentless competition. I would guess it's a good design. The flipside is that submini tubes were also created for AA5-style applications. I dismantled a late 50's RCA portable years back that used submini tubes, so it's quite possible that the general characteristics of the 12AV6 and the submini you used were pretty close.

Wish I'd kept that portable now, sigh. It had a wonderful 50's late deco case in red plastic.

I Don't see any reason why your choice should not work. It certainly would not take long to install and test it ... the only problem I can think of would be if the output of the circuit was too large a voltage for the controlled circuit. Should this occur, all you have to do is put in a resistive voltage divider. Almopst any old pot should do the trick since the feedback circuit is basically a low voltage very low current arrangement. Go for it .... if you have problems Get back to me .. I'll be glad to help.

When building a 2 stage transistor audio amp how do you keep the first stage from overdriving the final? I have been running simulations on workbench and it says that if I try to do this I be gett'n a big case of the ugly's. I tried and it was right...well it could of been wrong.

I have been experimenting with 2n2222's and I suspect that it must be the way the final is biased as compaired with the bias of the driver but I have no lititure around here as to how to set it up.

I have no trouble designing single transistor audio amplifiers (class A mostly) but it never occured to me that there would be a problem tieing two of them together (RC coupleing). Only wanted a few watts out but beginning to suspect that I need another type of transistor for the final, one that is capable of handling the input from the driver.

Yes, I know I can stick an opamp in there and be done with the whole thing but this is supposed to be a learning experience. :)

What I eventually want to do is slightly modify the HW-8 for speaker output. It currently is using an MPS A-20 transistor (what ever that is) for audio out into headphones. Was wondering if the A-20 would serve as a driver for a second stage?

God I get windy...I go away now.

6316. Re: Atlas 210X power output Question

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-28 00:00:00 UTC
From: leigh@rain.org
Message-ID: <4btb41$cm7@news.rain.org>
Source record: 108529
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

I've found my Atlas 210 to be EXTREMELY SWR sensistive, so you might take a closer look at your 75 meter antenna.

I sometimes do 40 meter mobile with a Hustler 40 meter coil and a SWR around 1:1.5. My Icom 735 will put its full 100 watts into this antenna, but the Atlas 210 will drop to QRP levels, unless I have a tuner inline, then I get full power out.

Even though it is a little drifty on warm-up, has no CW sidetone and awkward CW TX/RX switching, I like my little old Atlas 210. I bought it from a newer ham for a mere 50 bucks, one of the best radio deals I've stumbled upon.

I saw a posting on here the other day on converting a 2 channel Motorola Maxtrac(VHF High Band) to a 16 channel. I have access to both the software and hardware I need some technical advice on how to do it. I have
4 mobiles and 1 base station I use for my construction company and would like to convert them to 16 channel radios. I priced out new radios from a local guy and he wants $425 a pop for 16 channel ones(used, no less) and I spoke to a friend who says the hardware is only about $25 for each radio so I
figured this was the way to go. I really could use some help from you guys.
I'm really not a radio-guy, I'm a scanner-guy myself. Any help would be greatly appreciated. Thanx in advance.

Wayne,
Perhaps your second (Power) stage should be an emitter follower.
What you need is POWER not voltage gain.

And yes, do plan on a bigger transistor.

I admit I have a weird viewpoint on this. To me, the minimum
transient allows me to hear just a little bit more--a distinct
advantage in competitive pursuits such as pileups and contests.
Particularly from a 2nd floor apartment, where you are first
first or somewhere at the bottom of the pile.

Like the extra dB of gain from a bigger beam or better feedlines,
the extra expense is hardly worthwhile for talking to someone
who is ridiculously loud all the time.

Actually, if you are just interested in weak stations, one
alternative is to just clip out the strong signals. On the
other hand, you are now tossing out information that might
be useful.

Try finding one of those cheap weather radios that RadioShack sells
or used to sell. Replace the crystal, and tweak the coils. I think
the weather frequencies are around 160 Mhz.

Actually, I've seen basic VHF/UHF scanner radios for under $100. That
would be a bit easier, all things considered.

(Zack's scheme for multiple ADCs fed by different
attenuations of the input signal deleted...)

: But that's what dynamic range is all about. The above setup
: is exactly equivalent to one 16 Bit ADC plus 3 attenuators/AGC.

No, it's not _exactly_ the same. It's close, but there is always
at least 1 sample delay between the attenuators and the signal
processor connected to the ADC, and if the ADC is a delta-sigma
(an economical choice these days), the delay can be more than
30 samples. So, if you have to switch attenuators, the horse has
escaped from the barn before you have closed the door, so to speak
(write?). You end up with a period of some number of samples
where the ADC may be overloaded, because you didn't switch the
attenuator soon enough. (BTW, be sure to let a delta-sigma
recover long enough from an overload...)

But I'm still of the opinion that a decent 20-bit converter will
not be the limiting factor in an HF DC receiver signal path: the
mixer stage is most likely going to be the place where the largest
distortion products are generated, and if you set the gain such
that the 20 bit converter full scale is something like 0.5 volts at
the RF input, then in the HF bands at least I'd expect the RF noise
floor to be greater than the ADC noise floor, just from noise
received by the antenna. Maybe Zack has to deal with in-band
RF levels above 0.5 volts, but so far at least, I don't. And again,
I'd have to start worrying about the mixer dying at about that level
anyway. In summary, I think that using a decent 20 bit ADC with
proper level scaling in a DC receiver will give you performance good
enough that you will have to start looking at things other than the
ADC if you want further improvement.

Hi Chuck,

In article <30E1A985.E85@aries.scs.uiuc.edu>, "C. J. Hawley Jr." <hawley@aries.scs.uiuc.edu> writes:

>What happens here to the gasses? Do they change chemically and become >attached to something? Something like the getter? How did that work? <snip>

That's my understanding. The gas attaches to the getter and move it down the periodic chart a bit. Different materials work at different temperatures. I'm not up on small tubes that work at room temp. 3-500Z's have Moly anodes coated with Zirconium. That's the gray powdery looking stuff you see. It's built to run at around 1000 deg C, so the red color of the anode activates the getter! If you don't run "em red, they can eventually fail from gas!! That also limits shelf life, because how do you de-gas a gassy tube if the anode has to be operated at color to activate the getter?? (Well I know how, but it takes a variable HV supply and an adjustable positive grid bias, hi).

>If the plates are made hot, then this would work against the getter residue, so they >must not use getters in transmitting tubes?

Yes they use getters, just different getters with higher temp ranges.

> But, the plates would absorb gases if they are made out >Tantalum (and what other materials?) and became very hot. I read that >(Terman) Zirconium will absorb Hydrogen up to 350C but will give it back above that.
>Then if you have Zirconium also at 1400C it will greatly absorb other gasses. They
>can put two Zirconium filaments in at these two temps to clean up continuously.

Gotta watch mixing the wrong materials. The 8877 uses a heat dam of Tantalum discs on the fil/cathode assembly because Zirconium would poison the oxide cathode.
If they used a Tantalum anode as the exclusive getter in the 3-500 it would not cover the temp range. Everything gets too hot.

They do stuff differently depending on the application. I'm sure they often use a material just because they are comfortable with it, and they know it worked in other similar tubes, hi.

Phew.

Anyway, here's the rule Chuck. If you have a Eimac thoriated tungsten power triode with a gray powdery looking anode you betta keep that anode red. If you don't, you'll probably get gas in the tube. (and if you think a kindney stone hurts, wait til that happens)

>Is that better or worse than never going above 350C? Is that impossible in a >transmitting tube?

It is in a 3-500! The filament operates around 1500c and the anode should be run at around 1000c!

Cal,
A good place to start would be with the Exar databook. Using
any of their PLL decoder chips, such as the XR-2211, can be used as
a synchrnous AM demodulator (detector) when paired up with an analogue
multiplier, particularly the XR-2228. The data book shows the XR-2228
used with an XR-215 for synchronous AM detection, but myself I prefer
to use the XR-2211 in order to make a Costas Loop detector that will
also demodulate double-sideband suppressed carrier (DSB).

Zack, I have run headlong into the very same problem! I attempted to select 7805 chips and kind of bypassed the problem that way. Then I ran into the old low dropout regulator chip, LM2930. It was much better in general probably due to the PNP pass transistor within the chip. The problemn is that this chip is no longer available. If you would like to try one, I have a few left over. 73 Cliff Buttschardt W6HDO

The lowest noise commonly available regulator is the TL431.
If you want to go lower than this, you have to use a 1N821 reference
diode.

Zack,
I'm afraid not, at least for the moment. When I was a microwave
VCO design engineer at Omni-Spectra years ago, I was part of a long-term
test in which we evaluated SSB phase noise resulting from the use of IC
regulators. We found, after almost a year of on-and-off effort, that the
quietest regulator for a positive supply was the 723 with an NPN pass de-
vice, and for a negative supply the LM104 with a PNP pass device. I have
yet to hear anything different from those folks.

The IC720a needs a few mods in order to work on amtor.

The following is from the ICOM newsletter 35 of June 83, article by Roy Philpott DJ0OW, G3VCH.

Quote: All mods are to the main board, easily accessible on the top of the set. The modification consists of replacing C42 and C43 with 1uF. Also replacing C40 (1uF) with 0.47uF. This effectivly shortens the T-R switching, also it is necessary to remove the AF amp mute by placing a shorting link across C69 (there will be audio present on normal operation, but it doesn't cause a problem).

I did this mod when I had an IC720a and it worked fine with an AMT-1 terminal on "SSB" mode.

There is an article that was June 1987 p71 of QST that discusses a
simalar experiment using OSCAR satellites to DF stations. I would
suggest reading this article. It is also found on p92 of the ARRL
Satellite Anthology.
It does sound like an interesting project and I wish you the best of
luck.

6343. Using HP8690 with HP8410 Network Analyzer ???

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-29 00:00:00 UTC
From: nx7u@primenet.com
Message-ID: <4c1moh$a1d@nntp3.news.primenet.com>
Source record: 108549
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

The HP8410 Network Analyzer documentation specifically mentions the HP8620C as the sweeper of choice, even coming from the factory (at the time) with a control interconnect cable for the '8620.

Does anyone have any insight on if and/or how an HP8690 can be used as the sweeper in an HP8410 system??

Thanks in Advance,

Scott Townley
nx7u@primenet.com

Scott,
Sounds like you finally got that 8410 that you were looking for
earlier this year. Yes, you can use the 8690 as a source. According to
HP App Note 117-1, the only requirements for the sweep oscillator for the
8410 are:

1. RF Output - -15dBm to -6dBm.

2. Spurious signals should be at least -20dBc from the
carrier.

3. Sweep Characteristics: Uniform sweep rate that is variable
from 15 to 150 MHz/mSec. In addition, it is important that
there be at least a 3 mSec pause at the start frequency
prior to each sweep to allow the 8410 to attain initial
lock.

4. Phase Lock: To improve phase-lock operation at high sweep
rates the oscillator should furnish a voltage proportional
to its output frequency.

I've got a whold bunch of literature on this monster if you're ever
in need. Still owe you for the Ham Radio photocopies.

Steve Muther (stevem@w6yx.stanford.edu) wrote:
: I only suggested using video network feeds because there are many
: Ham type frequency counters etc. that use 3.58MHz crystals as the
: time base.

Note that most frequency counters which use color burst crystals for a time base "rubber" the crystal slightly, and divided down by a constant to get 100 or 60 Hz. These crystals are not run at the exact color burst frequency. There were some high quality time bases that did use the burst crystal at its real frequency and which drove a synthesizer to derive the standard frequencies. But most ham-type counters use the cruder method (e.g. the old DSI line of counters).

If you "calibrate" one of the simple divide down time bases by setting it to the exact burst frequency, you will actually be inducing error. These simple divide down time bases usually use an ASIC divider in an 8 pin dip to derive the working frequency. The divide constant is usually something like 35796 or 59660. National Semiconductor was often the manufacturer of the chip. Although I forget the part number, it can be found in NS data books.

6348. Re: QST IMP

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-29 00:00:00 UTC
From: William Kresl <wmkresl@townsquare.net>
Message-ID: <4c018a$4cg@spectator.cris.com>
Source record: 108554

QST's IMP is a BAYCOM modem design. It is also the basis for the PMP (POOR MAN's PACKET) modem that appeared about 4years ago in 73 Magazine that operated on the computer's PARALLEL PORT. BayCom and IMP are for the SERIAL PORT, and as such have access to a much broader base of SOFTWARE written to utilize this port (most programs that work with KISS modem can, with a driver use a BAYCOM modem).

Tho I briefly looked at the schematic of QST's IMP, here are my suggestions for dealing with any TI TCM3105JL based modem design. The chips RECEIVE BIAS input is a DC voltage into the chip that VERY critical to adjust for proper operation of the chip. All of the PMP/BAYCOM modems that I have built include a resistor trimpot wired as a divider, with one side of the pot to ground, other side to +5VDC and the WIPER of the trimpot goes to PIN 7 of the TCM3105JL chip (the RXB dc input). A rough DC voltage of +2.65vdc at this pin will get you started. The proper method of adjusting this voltage has been covered at length before (I wrote FEEDBACK letter to 73 Magazine describing in detail how do to it for the PMP modems using the PMPTEST program, a loopback cable and an oscilliscope). If you start with this value you should start receiving packets. I suggest you DON'T use the fixed voltage divider as it appears in the article (R7/R8). With there values of 56K and 68K ohms, I calculate approx 2.74Vdc at the RXB input...may/may not work. I base my experience on testing/building over 20 such packet modems.

I have written a program in BASIC and compiled as an EXE program called BAYTEST Version 1.00 that I distributed in a Newsletter and via some ham BBS's that will allow low-level testing of your BayCom modem transmit and PTT circuitry for various COM ports. Pawel Jalocha wrote a test program as well (I forget the name) to also test the BayCom modem receive circuitry.

Deriving power from the serial port thru the use of diodes D3 thru D6 to drive the U3 5volt regulator works for me, but MAY NOT work for ALL SERIAL PORT HARDWARE, most notably ZENITH LAP TOP serail ports. Especially with a LM78LO5 regualtor , a much better choice would be the NATIONAL SEMICONDUCTOR LM2900 series low drop-out regulators (maybe harder to obtain). If it does not work, you may need to use an external source to power the reglator (Battery/wall transformer).

Diodes D1 and D2 wired front-to-back are very important and should be wired close to the chip as they protect the RECEIVE INPUT, I've sizzled a few chips even with these diodes in place... cause unknown..but keep your receive AF level DOWN. Also, missing on the IMP is a proper 8ohm (or so) LOAD for the receive audio. I'd put a like value resistor at the junction of those diodes to ground.

Transistor Q1 supplies the PTT funtion, and the TYPE of radio you plan to tie this modem into will determine the configuration of this circuitry. Older radios with a dedicated PTT line switched to ground can simply be tied to the collector lead of Q1 (without the resistor R11). Newer radios switch the PTT in a differant way described in the article, so depending on the manufacturer of your radio will determine the final value of this resitor (typically 10Kohms).

Most of the Baycom modems utilized a special type of HIGH SPEED CMOS logic inverters to interface the +/- 12volts of the computers RS232 SERIAL port to the +5volt logic of the TCM3105JL modem chip (using 74HC14 or some such other device). The IMP uses an OP-AMP (U2) and a transistor (Q2) with a diode (D7). Should work fine.

I would suggest getting the Baycom software (version 1.5 from any ham BBS is shareware, version 1.6 is a COMMERCIAL PRODUCT sold by PACCOMM here in the USA), and starting using SERIAL PORT COM1 to play with (the default port). Changing to another port requires editing the BayCom parameter file SCC.INI and RE-COMPILING the new changed parameter file using the PARA command.

IMP looks like a nice project, but there are much better software alternatives then BayCom. Check out FBB of NPF or even NOS with the

appropriate driver software. Good Luck...73...

Check out the ramsey 2 Meter FM kit. It is only about 30.00 and work well.
It is synthisized, not crystal controlled, but when you take into account
that a crystal for you desired freq is going to cost you about 10-15.00
you can't go wrong with the ramsey kit. Thay are even avalable from Radio
Shack, special order.

Hello,
I need to modulate BF with a 38Khz carrier. Two solutions (may I'm
wrong ?) :

- 4 quadrant multiplier
- switches (diodes,...)

I want
- high dynamic (it's seem difficult with 4 quadrants multiplier)
- low distorsion (not the best point of switches)
- low drift and low noise.

What is the best solution ?
Have a nice day.

If you know how to design from Laplace -- take a bandpass filter. Subtract
from 1 -> band-reject.

For example, bandpass= a*s/(s^2+s*wn/Q+wn^2) ->
(Q s^2 + s(wn - a Q) + Q wn^2)

(Q s^2 + s(wn) + Q wn^2)

Or you can use an ordinary bandpass filter (e.g. standard IC), do the
subtraction with a diff amp.
There are many ways to approach this one.

-frank

c'mon, the guy asked a legitimate question. We don't have to care
why or agree with the motivation. I'm just bored enuff to try to
answer it.

You need two oscillators, one for the tone and one to clock the counter.
You need a counter that sits at 0 while the mic ptt is down, counts to 10 and hangs
there when PTT is up. Gate the tone off when the counter is at 0,4,6,10 giving a K
when PTT is released. Buffer PTT and hold it asserted while the counter is not at
state 10.

It will almost fit in a 20V8. I'm not sure you can build a reliable oscillator
without using two of the 8 logic blocks. Need to think more about that.

If you'd settle for a courtesy beep, it could be done with a dual one-shot.
It's a five minute hack. It's at least a start.
Have fun, miker

Check out 'fftmorse'. You can find it at several FTP sites in the hamradio area (try ftp.cdrom.com or http://www.arrl.org/).

There is little I have found with source code. You can also try 'svgafft'. This is Linux program that uses the Sound Blaster for a digital oscilloscope and includes all the sources... the FFT routines are in fortran.

The Station Manager of WELI radio in Hamden, CT. said I had a wire tap in my tooth. People including children were repeating things that I was saying and that is how he explained it.

People recieving... are recieving my thoughts I discovered in much the same way a modem works decoding that frequency into thoughts and are very accurate. Children do this all day long here as I sit.

I pick up the phone when modeming and hear that sound, and during the night as I sleep I hear that same sound, but at a higher frequency in my head.

I was told by the FCC that radio telephone is doing that and that they are not licensed to recieve but only to broadcast.

Try the index in your university library. It's a pretty mature field. Don Lancaster has a good introductory book on (audio) filters. Nov 95 QEX (ARRL, Newington CT) has an article on a notch filter to remove an AM BC station.

Umm, what sort of notch filter? Audio? RF? What power level?
Analog or digital? Passive or active? What sort of specs are you
looking for? (Attenuation, stop-band width, flatness of the non-
rejected portion, ...)

Cheers,
Tom

6363. VCO regulator chips

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-29 00:00:00 UTC
From: Zack Lau <zlau@arrl.org>
Message-ID: <4c1cn5$4pq@mgate.arrl.org>
Source record: 108569

Is there a better chip to use than the ancient 723 regulator chip? The National Databook lists its output noise as typically 2.5 uV rms between 100Hz and 10 kHz. The 78L05 and LM317 are much worse (40 uV, 0.003 %)

I don't think it helps to run VCOs off of noisy power supplies if you are trying to minimize phase noise.

I use a large capacitor (I.E. 470uf across 100n) in series with some resistance and an ordinary regulator (78L08). This provides a noise free supply in my designs.

There is a in apartment antenna kit out on the market for the 11 Meter CB band. It uses fiberglass loaded whips for the main radiating element and ground planes. You might want to adapt the same idea for your 10 Meter station.
Hope this helps..... :)

Yep, it's a problem. In fact, it can even be a
problem for power or references for audio amplifiers,
if you are trying to get to really low noise performance.
It's a problem with voltage references as well as for
regulators. What I've done with some success is filter
the output of a voltage reference with an RC filter and
feed this to an op amp follower; the op amp might include
an emitter follower buffer in its feedback loop, in order
to get enough output current. You might also get by with
an LC filter on the output of a regulator, but I've never
had the space for large enough L's to do much good in the
10s of Hz range. If you use the op-amp follower approach,
use a low-noise op amp, and make sure its power supplies
are reasonably clean. If you use a single pole RC as the
filter between the reference and op amp, you can get it
to settle faster if you put a diode across the R. If you
aren't worried about filtering down to the 1Hz range, this
might not be a problem but it can be if the RC time constant
is several seconds. Of course, you can make the filter
a 2-pole active one, feeding the op amp output back
appropriately, and that helps a lot in getting good filtering
but reasonable turn-on times.

>internet searches but I haven't found much.

Michael,

In the older Handbooks there was a schematic and plan for a 2 million bit per second digital link. Would you be satisfied with a setup that would take the audio, turn it into digital data. Then send it and convert it back to audio? This way multiple audion channels can be sent over the same link. Also if this is to be used as a link between a repeater transmit and receive sight, the control signals from the receiver don't have to be encoded as tones.

This unit can operate either at 10 GHz like you mention or it could be made to operate at the K band at 24 GHz. Claimed range with parabolic antennas is approximately 20 to 30 miles, line of sight.

>is the normal cassette motor speed. All suggestions & solutions
>appreciated.

In order to double the speed, you will either need to replace the
motor or change the mechanical relationship between the motor and
capstan. While some reel/reel machines have used sleeves over
the capstan for this purpose, that may not be a viable option with a
cassette recorder due to space limitations in the cassette shell
itself. The only other options are to either install a larger motor
pulley or a larger flywheel. Neither is easy, although of the two,
having a custom motor pulley machined is the least difficult.

Once the tape speed is mechanically doubled, an adjustable voltage
regulator circuit can be used to reduce it as necessary.

This advice is offered relative to the typical DC motor-powered,
belt driven cassette mechanism. Other types, particularly direct
drive transports, those based on AC motors, or those that are
belt-drive servo-controlled, may not be readily adaptable.

Source record: 108494

Bob,

Many thanks for the additional information, and for the diagram worth a thousand words.

I don't know what response you have had to your posting, but you have certainly got me interested, and I'd be most grateful for any further info you can find time to post, please.

You triggered the memory cells, and over the Christmas period I dug out an old copy of a UK magazine, Wireless World (Jan 1984 !) which had an article on a home made X-Y plotter. This provided some alternative ideas for the X and Y mechanism. using aluminium (sorry, aluminum!) u-shaped channeling and ball bearings instead of ground rods for one side of the table , and tap (faucet) washers as wheels for the other side, thus avoiding the need for accurate alignment of the rods. I guess at that time scrap printer mechanisms were not available.

Being a plotter it used only a solenoid for pen up/down.
I have been thinking about how to make the Z axis control with the limited facilities I have. The movement required is only a little more than the PCB thickness, but I see problems with limiting sideways play whilst at the same time keeping the mass down. (Until I saw your diagram I wondered if you were moving the board in the X-Y planes whilst keeping the drill position fixed, which is another way of doing it - but there is still the problem of Z axis sideways play). I'd be interested in your solution to this.

I also downloaded a useful stepper motor tutorial file from armory.com/pub/user/rstevew. Wonderful thing, this Internet.

I would be very interested in the pcb/software idea, but I think there might be problems with the multitude of different stepper motor types around, with their differing drive requirements. A kit to cover all kinds would be tricky, I would think. However, anything you can make available, diagrams or software, would save a lot of effort reinventing the wheel so to speak, but I appreciate your boss would probably not be too keen!

Anyway, thanks again, it's good to know that in this black-box, throw-away age there are still people prepared to have a go at making things themselves.

Best wishes for 1996.

Tom Bratton

There's an ultra low-noise and stable
regulator design featured on page 375 of
"The Art of Electronics" by Horowitz and
Hill (2nd edition). It features the
following specs:

Noise and ripple < 1 uV
Temp coeff < 1 ppm/degree C
Output Z < 1 uohm
Drift < 1 ppm/day

At these levels, you'll need to pay
particular attention to circuit layout
and electronic package (crosstalk, EMC,
etc.)

Julian Warhurst
warhurst@aol.com

I am in the process of designing a low baud rate data link for a remote instrumentation station. I had considered using the 49Mhz RC/Cordless Telephone or the 27Mhz "Citizens Band" frequencies simply because of the availability and low cost of the hardware. However the range of about 2 miles proved inadequate for a 100mW 49Mhz transmitter, but a 3 watt 27Mhz hand held transceiver worked perfectly.
Here are my questions:

Are there any restrictions on transmitting data (300 baud FSK) on 27Mhz above the 100mW power threshold?

Is the 49Mhz band limited to < 100mW or are there exceptions?

This would be a intermittent duty application, so it wouldn't be "hogging a channel".

I would sincerely appreciate any feedback you can offer.

Since this is probably of general interest, I decided to post as well
as email.

You did not specify a frequency range so I will give you two common
circuits which have a genuine null (0 transmission) at a single
frequency. These are three terminal networks. In both cases the
selectivity skirts are very steep, the phase shift goes quickly from
-90 to +90 degrees near null, the driving impedance is ideally 0 and
the output impedance ideally infinite. You can however compensate for
real input and output impedance if you wish.

At radio and high audio frequencies a Bridged-T has been used. This
consists of an inductor L, two capacitors each with a value of 2C and
a resistor R. The input and output terminals are the two ends of the L
with a common ground for both terminals. The two capacitors are in
series and bridge the inductance. The junction of the two capacitors
is tied to R whose other end is tied to ground. The null frequency is
the parallel frequency of the equivalent LC network, i.e. where the
reactance of the inductor is equal to the reactance of the two C's in
series. This gives:

2*pi*null-frequency*L = 1/(2*pi*null-frequency*C).

Since the inductance has a finite resistance, the resulting undesired
phase shift is compensated by R as follows:

4R = 2*pi*null-frequency*L * Q where Q is the inductor reactance
divided by its resistance.

At audio and supersonic frequencies, a network that is referred to in
the literature by two different names is used--the Twin-T and the
Parallel-T.
This consists of three resistors and three capacitors. One T is made
up of 2 resistors of value R between the input and output terminals
and a capacitor of 2C tied between the junction of these two resistors
and ground. The other T has two capacitors of value C between input
and output and a resistor of value R/2 between the juction of the two

capacitors and ground. The null frequency is where R equals the reactance of C, i.e.

R = 1/(2*pi*null-frequency*C).

Speaking from experience, it is very difficult to get the null frequency of the Twin-T exactly where you want it due to the tolerance of components. A little known fact is that you can make the resistor (that has a value of R/2) a potentiometer and vary the null frequency (still a true null). The wiper of the pot goes to ground. One of the other ends of the pot is connected at the junction to the two series capacitors and the other end goes to the capacitor which has a value of 2C. I saw this long ago in a Russian technical journal, but have used it many times.

Although there are other null networks, these two are the most common.

Colin Horrabin, G3SBI, designed a low-noise 8V-9V regulator for some experiments he's been doing with with low-phase noise oscillators. The circuit is described on p 55 of the RSGB Radio Communication mag., July 1994. It uses a couple of VN10KM FETs and a BC184L. Zack should be able to find a copy at the ARRL. Colin's oscillator circuits are also described, which are well worth looking at; they use stripline resonators.

6388. 4$ale - Tek Spectr Analyz

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-30 00:00:00 UTC
From: morkbj%DFC@dfmail.usafa.af.mil
Message-ID: <morkbj%DFC.6@dfmail.usafa.af.mil>
Source record: 108501
Cross-posted to: sci.electronics,rec.radio.amateur.homebrew,rec.radio.swap

A rare golden bird - super condition!

Tektronix spectrum analyzer, composed of the following components:

- 7L12 1.8 GHz spectrum analyzer in a 7613 frame, selectable
storage scope or normal trace.
- a spare 7603 frame, but display tube is cracked.

Covers 100 KHz to 1.8 GHz with internal mixer.

Resolution Bandwidths of 300 Hz to 3 MHz, with Frequency Spans
(dispersion) from 500 Hz/div to 100 MHz/div.

On screen vertical dynamic range: 80 dB. Log 10dB/div, Log 2dB/div,
and Linear settings selectable.

Sensitivity is +30dBm to -100dBm at 300 Hz resolution bandwidth.

Sweep time is 10mS/div to 1uS/div, or automatic depending on the
resolution and dispersion settings.

Tucker sells just the 7L12 plug-in for $3995, but street prices seem to
check out at 1/2 to 1/3 of Tucker's --about $1300 for the 7L12 alone in
recent issues of Nuts & Volts. I offer the entire package for $1199,
including the second mainframe for spare repair parts.

Ask for Brian at 719-472-0707 (Mountain time).

6389. Sending digital data on 27/49Mhz

Newsgroup: rec.radio.amateur.homebrew

Julian Warhurst
warhurst@aol.com

I am in the process of designing a low baud rate data link for a remote instrumentation station. I had considered using the 49Mhz RC/Cordless Telephone or the 27Mhz "Citizens Band" frequencies simply because of the availability and low cost of the hardware. However the range requirement of about 2 miles proved excessive for a 100mW 49Mhz transmitter, but a 3 watt 27Mhz hand held transceiver worked perfectly.
Here are my questions:

Are there any restrictions on transmitting data (300 baud FSK) on 27Mhz above the 100mW power threshold?

Is the 49Mhz band limited to < 100mW or are there exceptions?

This would be a intermittent duty application, so it wouldn't be "hogging a channel".

I would sincerely appreciate any feedback you can offer.

6390. !SUPER KEYER II - MYSTERY SOLVED!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-30 00:00:00 UTC
From: tom.alldread@minfox.com
Message-ID: <9512311820198630@minfox.com>
Source record: 108503

Greetings All:

I built the now superseded CMOS SUPER KEYER II from the Nov.
1990 issue of QST. I use it with a Bencher paddle and have been very
pleased with its operation with the exception that occasionally it
seemed to discharge the batteries pre-maturely.

I have checked the battery drain several times in the past to
confirm that the micro controller was in fact going into the power
down sleep mode when left idle. Each time I did this test was after
replacing the batteries and I observed the drain fall off to a few
microamperes a few seconds after connecting the the new battery.
Of course in the process of changing the battery I reset the
controller and did the test in the normal power up keyer mode.
Everything appeared fine and I remained mystified.

Finally I discovered the cause. I had been away on a trip for
five weeks and had just put in a new set of batteries prior to
departure. Upon returning I found the batteries (3 AA alkaline cells,
BTW) discharged. I remembered last using the keyer in the hand key mode
for finalizing my ladder line antenna tuner adjustment (conveniently
done with momentary ~key down~ in the hand key mode). I had left the
SUPER KEYER in the HAND KEY mode.

I have found that my SUPER KEYER II does not switch into power
down when it is left in the HAND KEY mode. I wonder if anyone
else has identified this in the past or if anyone knows of a change of
firmware in later chips that corrected this bug? I wonder if the new
version III has a similar problem?

6391. TRC-505 (49 MHz) to 6m mod?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-31 00:00:00 UTC
From: kk5ni@rapidramp.com
Message-ID: <4c4pb6$jmn@alterdial.UU.NET>
Source record: 108504

I picked up a TRC-505 FM Transceiver at the Radio Shack outlet in Ft. Worth last week for $3. Strangely enough, it's in working condition.

It's my understanding that it would be possible to modify this radio by "simply replacing some crystals...etc." Can anyone provide a little more detail and/or explain the function of the different components? Here's a partial listing from Tandy's support pages:
L2 CA1179 COIL,RX RF 50MHZ
L3 CA1180 COIL,DETECTOR 455KHZ
L4 CA1181 COIL,RECEIVER OSCILLATOR
L5 CA1182 COIL,TX POWER 48MHZ
X1 CX0044 CRYSTAL,10.245MHZ
X2 CX0045 CRYSTAL,39.130MHZ
X3 CX0046 CRYSTAL,16.610MHZ

10.245+39.130+0.455 = 49.830 MHz = frequency on label
I have now summarized the extent of my knowledge concerning the inner workings of this radio ;)

Followups or e-mail on this subject would be greatly appreciated
Thank you kindly,
Robert Clark

There has been information in one of the Microwave Update documents
that are available from ARRL. The way to do this is to FM modulate
the transmitter by using the varactor or by varing the gunn voltage.
the receiver operates as a converter to an FM receiver. the two
gunn oscillators are offset by the FM receiver frequency. This works
great for one way transmission. For two way operation it still works
as you can use the gunn to transmit and receive at the same time but
you will hear your own transmissions as well as the distant end. This
arrangement has been used by many microwave operators

Message-ID: <4c52s2$8dv@calweb.calweb.com>
Source record: 108507

I forgot to mention that you should use wide band FM. The Gunn units
will drift too much for narrow band. You might look for the old style
TVRO receiver units. They used a tuneable converter at the antenna
and a fixed frequency IF receiver at the TV set. The IF was usualy
70 MHz and the bandwidth was about 20 MHz. Even though they were intended
for TV you should be able to use them for voice.

The Microwave Update artice was in the Microwave Update 1991 on page
259. It described modification of a Radio Shack FM receiver to change the
frequency to 30 MHz for use with a Gunn unit.

:
: I'm looking for an add-on circuit to vary the speed of cassette recorder
: motors. I want to be able to vary the speed from 2*x to x/8 where x
: is the normal cassette motor speed. All suggestions & solutions
: appreciated.

European meteor-scatter operators have been doing this for years, receiving Morse at 200+ wpm and slowing the tape down for playback.

Some cheap cassette motors are mechanically governed and there's very little you can do to change the speed electronically. However, some models are controlled by a constant-voltage regulator and there's generally a trimpot to set the speed. By bringing the feedback potentiometer out to a front-panel control you can often adjust the speed within the kind of range you want.

The maximum speed depends on the risks you want to run by overloading the motor. The minimum speed depends on friction, mainly within the tape cassette itself. You can often reduce the minimum speed by using a pulsed-DC system; for circuits, check out the books on electronics for model railroads.

>Electroncs went years ago, selling kits with articles.

Hello, Jim,

I don't kwow if I would go *that* far. First, ARRL doesn't sell the kits; the authors do. From the feedback we have received from readers, most readers *prefer* construction articles that have kits. And, in most cases, even if a construction project has a kit, the builder can still dead-bug it, if he or she chooses. This tuner article is almost an exception to the rule, in that it requires a part that is available only from the author. However, the author will gladly sell the progrmammed IC only for those who want to locate all the other parts themselves. (I wonder if *anyone* will take him up on the offer; I want the kit! :-)).

6400. silver plating, help

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-12-31 00:00:00 UTC
From: dallen@cei.net
Message-ID: <4c6na7$68j@ren.cei.net>
Source record: 108513

I am attempting to silver plate a brass strip 1"x9". It is to be
used as a 1/4 wave strip line in the output of an amplifier I'm building. I
dimly remember reading an article once describing the use of exhausted
black and white photographic fixer as the electrolyte for silver plating.
I do a bit of photograhy and have old fixer available. The fact I can't
find the article only made me determined to figure out what the method
outlined was. I have played around a bit and found that I can sucessfully
deposit a nice even coat of silver on a piece of brass. My problem is mixed
results getting the silver to adhere well. I have managed to get
what I'd consider proper plating on an object, but later using the same
parameters the silver film can be rubbed off. I have played with varing voltages,
currents, and methods of cleaning the brass prior to plating. Here are the
parameters I'm using:
1) Voltage source is a 1.5v dry cell.
2) Series resistance of 12k in circuit giving a current flow of 1 milliamp
or so.
3) Fixer saturated by loading it up with old photographic paper prior to
plating.
4) Silver donor is an old piece of solid silver silverware.
5) Cleaning the brass with a scotch-brite pad then wiping down with alcohol
to de-grease.

Using the above, I can get a wonderful even deposit of silver. As I wrote
above the only problem is with the silver being bonded well to the
brass item. Probably half the time things work well, the other times not so
well. Mr Murphy allows me to plate a scrap perfectly but the item I need to
plate is giving me fits. Any ideas, suggestions or even pointing and laughing
in my direction are welcome.

Most of the late '80s Radio Amateur's handbooks have a detailed description of what you are looking for. The design is actually equivalent to the system sold by Advanced Receiver Research. Full duplex audio is one of its more interesting features. ARR sells a search and lock board so the system recovers from fades etc.

The Fairchild data sheet for uA723C lists 2.5 uVrms with Cref=5 uF in the reference divider and 20 uVrms without Cref. It seems that the real culprit is the voltage reference and not the error amplifier and output stage. However, I could not find at what output voltage these noise voltages are measured. If the main sourc of noise is the voltage reference, you get much prettier figures at 2 V output than at 36 V output.

Tom Bruhns (tomb@lsid.hp.com) wrote:

The 723 contains a separate voltage reference and a differential amplifier and an emitter follower in a smaller package count. Filtering can be inserted between the reference voltage source and the differential amplifier.

> Ifou use te op-amp follower approach,
> use a low-noise op amp, and make sure its power supplies
> are reasonably clean.

Agreed. It is no use to clean up the refeence and then connect a noisy op-amp (such as 741 or TL081) as the regulator, since the noise from the op-amp alone can be greater than 2.5 uV at 10 kHz BW. Fortunately, op-amps with noise densities below 3 nV/sqrt(Hz) are available at reasonable prices, so you could get 0.3 uV at 10 kHz BW if you had a clean reference.
